In view of this fact, the Board of Health adopted several measures which, it was felt, would be of advantage in saving the lives of prematurely born babies. First, a careful survey was made of all the hospitals in the city to determine whether or not they were provided with adequate facilities to care for the prematurely born infant. Each hospital was rated on a basis of the facilities available. The institutions that lacked facilities were encouraged to make corrections, and they equipped their nurseries to meet the needs for the proper care of premature infants. As a result of these endeavors, several of the hospitals constructed

a nurse is assigned to cooperate with the doctor in any way she can to give the infant adequate care.

Third, an incubator ambulance was provided to transport these infants, without charge, from homes

* In tables 2 to 10 inclusive the figures refer to premature infants who died.

Second, the Board of Health passed a regulation making premature births reportable at once by telephone and requiring confirmation in writing within twenty-four hours. As soon as such a birth is reported,

² Hess J. H. The Care of the Premature Infant. Clifford S. H. Reduction of the Infant Mortality. J. Pediat. 6: 139 (Aug.) 1934. Blackfan K. D., Yagiou C. P. and Wyman Katherine M. The Premature Infant. Am. J. Dis. Child 40: 1175 (Nov. part 2) 1933.

Some heated beds were secured to be sent, whenever they are needed, to hospitals not equipped with them. These heated beds are also sent to homes for premature infants requiring them.

The Board of Health, with funds supplied by the Mayor of Chicago, established a mother's milk station where breast milk is collected and made available for premature and other infants who are in need of it and whose parents are not able to pay for it.

In connection with the care of the premature infant, instructions were sent to the various hospitals. These stated, especially, the need for the prevention of hand-borne infections. A booklet on the care of the premature infant, written in simple language, was prepared. This is sent to mothers who have prematurely born infants, as well as to all physicians, nurses and others who desire the material.

ANTEPARTUM CARE

Of the 795 premature infants who died, the antepartum care given was ascertained for the mothers of 786 infants. Reports indicate that 389, or 49.5 per cent, received antepartum care that conformed to the minimum requirements.

nation had been made. This, of course, eliminates the possibility of discrepancies between the cause of death given on the certificate and that found on autopsy. Only a few of the records showed whether or not the autopsy confirmed the clinical diagnosis.

MALFORMATIONS

Malformations were present in sixty-one, or 7.7 per cent, of the premature infants who died. With few exceptions these malformations were serious enough to be the cause, or contributing cause, of death. Cardiac and cephalic malformations were the most frequent.

In fifty-seven, or 7.2 per cent, of the premature infants, the physical defect was so severe as to be incompatible with life. Many infants were affected with multiple malformations.

MORTALITY RATE

In 1935, 1,862 infants out of 49,425 live births were classified as being prematurely born. This is a rate of 37.7 premature births per thousand live births. Of the premature infants, 795, or 42.7 per cent, died during the first month of life. Of the 795 prematurely born babies who died, 450 were stated to have died from prematurity alone.

Of the 450 infants autopsies were performed on eighty-four. In thirty-two of these the cause of death was found to be other than that on the death certificate. Twenty-seven of these thirty-two deaths were directly due to atelectasis, one to syphilis, two to bronchopneumonia, one to a birth injury, and one to a congenital malformation and not to prematurity, as had been stated on the death certificate. In view of this fact it is fair to assume that, in many of the remaining infants on whom no autopsy was performed, some condition other than prematurity caused the death.

There is a great deal still to be done if the deaths from prematurity are to be further reduced. Endeavors to save the infants who die during the first forty-eight

the prematurely born infants who died, 62.4 per cent weighed from 1½ to 4 pounds.

Of the 795 premature infants of whom we had knowledge and who died under 1 month of age, 74.8 per cent were born in Chicago hospitals, 24.8 per cent were born at home and 0.4 per cent were born outside the city, en route to a hospital, or else the place of birth was not known.

hours, especially, must be exerted during the prenatal period and toward the control of factors operative at the time of delivery.

Further analysis of the figures obtained through the investigation of the premature deaths revealed some interesting facts.

FIFTH WEIGHT, PLACE OF BIRTH

The birth weight of 742 premature infants who died is shown in table 10. Of this number as shown in table 10, 62.4 per cent weighed less than 5 pounds. Of

PATHOLOGIC CONDITIONS AT BIRTH

Three hundred and twenty-two, or 40.5 per cent, of the premature infants who died had clinically one or more of the conditions listed in table 11. Atelectasis, hemorrhage of some type, and asphyxia were the conditions most frequently present.

RESUSCITATION

Information as to whether or not resuscitation measures were used was obtained for 794 premature infants who died, and resuscitation was used for 251, or 31.6 per cent.

A catheter (tracheal) for aspirating the pharynx or larynx was used in 52.2 per cent of the premature infants who died and who required resuscitation, as shown by table 12.

The various methods of resuscitation were used 465 times in 251 babies. Methods which, in general, are not accepted as being satisfactory, such as slapping, swinging, spraying with ether, artificial respiration, alternate hot and cold baths and similar violent efforts to induce breathing, were used 149 times, or in 32 per cent of the total. The administration of drugs such as epinephrine or other cardiac and so-called respiratory stimulants was noted in sixty-five cases.

The most frequent difficulty encountered in the child at the moment of birth was a lack of adequate respiratory function due to atelectasis. Physiologically the lung is in an atelectatic state in the new-born. There

is a variety of abnormal conditions which may tend to cause the atelectasis to continue. In premature infants, an undeveloped respiratory center and weak respiratory muscles may delay or prevent the establishment of breathing. Cerebral compression or hemorrhage may have the same effect. Asphyxia, from this or other causes, such as compression of the cord, detachment of the placenta or aspiration of fluids, is an urgent condition to be met promptly.

The first movement in the respiratory act is, of necessity, inspiration. Unless the mucus or fluid in the nose, pharynx, larynx or trachea is withdrawn by the use of the catheter (tracheal), with continued breathing this mucus may be drawn into the lungs and may result in asphyxia. Therefore the immediate and proper use of the catheter (tracheal) should be the first step in the attempt at resuscitation in all instances.

PLACE OF DEATH

Five hundred and seventy-six premature infants, or 72.5 per cent, died in the same hospital in which they were born and had never left the institution, 105, or 13.2 per cent, were born at home and died at home, eighty-seven, or 10.9 per cent, were born at home but died in a hospital.

| None | 9 |
| Unknown | 6 |
| Total times types of care were given | 1,570 |

TYPE OF CARE

Of the 795 premature infants who died, 565, or 71.1 per cent, were placed in an incubator at once, as is shown by table 14. Of the 230 who did not receive immediate incubator care, forty-six received it within a few days. In addition to incubator care, oxygen, external heat and stimulants were the most frequently used forms of treatment for premature babies.

The mortality rates from various institutions show the advantage of caring for premature infants in

specialty equipped nurseries under the supervision of an expert personnel. Resuscitation measures were instantly operative, adequate heat and breast milk provided, and the infant disturbed as little as possible, at those institutions where the mortality rates were low.

An attempt was made to evaluate the care which the babies received, as is shown in tables 15 and 16. The care of sixty-four premature babies who died was judged as inadequate by the investigator. The main

| Total | 32 | 23 | 4 | 5 | 64 |

reasons for this judgment were lack of incubator care, lack of breast milk, the use of questionable obstetrics, and general inadequate care and attention.

SUMMARY

A review of the mortality of premature infants under 30 days of age in Chicago for 1935 shows that the adoption, for city-wide use, of measures shown by Hess to be effective in hospital practice has brought progress in saving the lives of these babies. Most of the deaths of premature infants occurred during the first twenty-four hours (69.7 per cent). This is almost double the percentage of full-term infants who died during the first twenty-four hours (37.6).

Lack of proper antepartum care is a large factor in the production of high mortality rates in premature infants.

Wassermann tests on pregnant women are not made with nearly the frequency with which they should be carried out.

The improper use of analgesics, anesthetics and oxytocics may account for some of the mortality from prematurity. Pathologic conditions in the mother, such as toxemia, placenta praevia, infections, such as pneumonia and syphilis, are factors in almost half of the deaths of premature babies. The most frequent causes of death associated with prematurity were atelectasis, cerebral hemorrhage, malformation and bronchopneumonia.

Methods of resuscitation in general not accepted as being satisfactory were employed 149 times. The use of proper resuscitation methods will help reduce the mortality of premature babies.

CONCLUSION

The problem for the future consists, especially, in more extensively controlling the causes of death at the time of the birth of premature babies, as well as those conditions operative during the antenatal period. In other words, there is need for extension of antepartum, obstetric and postnatal care.

The proper antepartum and obstetric care for all pregnant women should bring about a marked reduction in the number of deaths not only among premature babies but among all infants who die under 30 days of age, as well as the number of stillbirths. The Board of Health will continue to extend its efforts along these lines during the coming years.

To find ways and means for further reducing infant mortality, data concerning the exact causes for these deaths must be at hand. Such data can best be obtained by a careful personal investigation of each death by a trained medical investigator. If such investigations were conducted by boards of health in many communities and the figures compared, much informative material would be made available.

THE DIFFERENTIAL DIAGNOSIS OF SALICYLATE POISONING AND DIABETIC ACIDOSIS

REPORT OF A CASE

BYRON D. BOWEN, M.D.

JOSEPH F. ROUFA, M.D.

AND

ORRIS W. CLINGER, M.D.

BUFFALO

When Langmead¹ in 1906 reported eight cases of salicylate poisoning in children, two of which were fatal, he called attention to the similarity of these cases to diabetic acidosis. Likewise, he referred to the term 'salicyl-dyspnea,' which Quinke had used in 1882, when he too had apparently noted the resemblance. Since that time this observation has been abundantly confirmed. It would appear, however, that the syndrome produced by overdosage of salicylate has not been sufficiently stressed to make it common knowledge. Standard textbooks and systems of medicine, as well as key treatises on the subject of diabetes, do not mention it. Two of the textbooks on pediatrics which we examined described it briefly under "poisons." Our object in restating this problem under the foregoing title is again to call attention to this similarity.

REPORT OF CASE

History.—H. U., a boy aged 18 months, was sent to the Children's Hospital on the evening of Jan. 31, 1936, by Dr. B. M. Bukowski, with a tentative diagnosis of diabetic coma. It appeared that restlessness, irritability and heavy breathing had been observed three days previously. On the following day these symptoms were aggravated and vomiting had become persistent. On entrance the child had not retained food or fluid for thirty-six hours. It had become stuporous about six hours before admission. The mother said that the child had been exceedingly thirsty all during this illness and prior to the acute illness had had a voracious appetite.

Bedside Examination.—The child was well nourished and well developed. A high grade hyperpnea (Kussmaul breathing) was present. The skin and tongue showed evidence of considerable dehydration. The child cried when disturbed but soon

fell asleep. The pupils were dilated and the eyeballs were noticeably soft. There were no abnormal neurologic signs or evidence of meningeal irritation. The temperature was 99.2 F (rectal), pulse rate 140 per minute and respiration rate 40. The urine reduced Benedict's solution (3+) and showed a strongly positive ferric chloride reaction.

Course.—Shortly after admission the child was given 5 units of insulin and 400 cc. of 5 per cent dextrose in physiologic solution of sodium chloride subcutaneously. An hour later the insulin was repeated. The blood sugar, taken before the administration of insulin, was then reported to be 87 mg. per hundred cubic centimeters. Two hours later the child's eyes were "starey," and 10 Gm. of dextrose in a 50 per cent solution was administered intravenously. The probability of diabetes seemed to be eliminated. An acidosis from some unknown cause, a lesion of the central nervous system or some type of poisoning was then considered. The carbon dioxide capacity of the blood plasma was found to be but slightly reduced (50 volumes per cent). This seemed to rule out acidosis as the cause of the hyperpnea. The spinal fluid (20 cc. removed without difficulty, under pressure, which, unfortunately, was not measured) was clear, contained no increase in protein or cells, and reduced Benedict's solution in fifteen seconds.

The following day the child was less drowsy, but still restless, and cried frequently. He had taken milk and water by mouth, and vomiting had ceased. The respirations remained at 40 per minute but were noticeably less deep. The urine did not reduce Benedict's solution, but the Gerhard test showed the characteristic violet color of the salicylate reaction. The spinal fluid, which had been removed the day before, was also found to show the same reaction to an extreme degree. The sodium nitroprusside test on both the urine and the spinal fluid was negative, as was the stomach washing obtained the previous night.

On the second day the restlessness and hyperpnea had entirely disappeared. The child was discharged from the hospital three days after admission clinically well.

Subsequent investigation revealed that the parents had found several "anacin"² tablets in a place that would have been accessible to the patient. Also it was determined that the child, on the day before the illness, had taken a sip of well diluted oil of wintergreen.

Additional Laboratory Examination.—The admission specimen of urine showed considerable albumin (2+), but none was present in the specimen obtained before discharge. The blood count, which was taken on admission, showed some unexplained hypochromic anemia. The hemoglobin was 52 per cent (Sahli) and the red blood cells numbered 5,900,000. The white blood cells numbered 17,700 per cubic millimeter, 67 per cent of which were polymorphonuclears. The blood smear showed considerable anisocytosis and hypochromia.

COMMENT

It is well known that diabetes in children may not be suspected until symptoms of acidosis appear. One who is confronted with a clinical state such as we have described may be led to the error as we were, of treating such a patient for diabetic acidosis, unless facilities for doing blood sugar and carbon dioxide determinations are promptly available. It is well known that the urine of patients who are taking salicylates reduces copper solution, often quite completely. Also the laboratory technician who is unacquainted with the Bergundy red reaction of acetoacetic acid and the violet color produced by salicylates in performing the Gerhard test may unwittingly report the presence of diacetic acid. Starvation under such circumstances may produce ketonuria (sodium nitroprusside test). When such an emergency exists there is not time to differentiate the reducing substance of salicylate and dextrose in the urine by the fermentation method.

The permeability of the meninges to salicylate has been known since 1878 when Livon and Bernard³

² Anacin tablets are reported to contain a ethylsalicylic acid quinine sulfate, caffeine and acetaminophen.

From the P. T. S. General and Children's Hospitals and the University of Medicine at Buffalo, N. Y.
¹ Langmead, F. Salicylate Poisoning in Children. Lancet, 1, 1922, 1000-1001.

demonstrated it in dogs by the ferric chloride reaction. Both Hitch⁴ and Dyke⁵ found salicylate in the spinal fluid in their cases by this method. The pressure of the spinal fluid has been measured in but few instances. In Madisson's⁶ case it was 190 mm of water, in Dyke's⁵ 180 mm, and in Mikulowski's⁷ 150 mm. The examination of the spinal fluid for salicylates at the bedside might be decidedly helpful in making a differential diagnosis.

Dyspnea is an important symptom of salicylate poisoning, and it is largely because of this hyperpnea that acidosis of diabetic or renal origin is often suspected, unless there is a clear history of the ingestion of salicylate. Sylla⁸ followed the pulmonary ventilation in his patient with acetylsalicylic acid poisoning after the second day. It fell from 37 liters per minute to 11 liters on the third day and was normal, 5 liters per minute, on the seventh. The basal metabolic rate was plus 33 per cent on the third day and normal on the seventh.

The cause of this dyspnea has been widely discussed. Naturally, because of the Kussmaul type of breathing, it was thought to be caused by an acidosis, particularly since all investigators agree that there is some reduction of the carbon dioxide capacity of the blood plasma in salicylate poisoning. Many observers have noted the disparity between the degree of hyperpnea and the alkali reserve. Veil and Graubner,⁹ Gebert¹⁰ and Odin¹¹ found with this an increased p_H of the urine. They suggest that salicylate has an irritative action on the respiratory center which produces hyperventilation. Thus, in turn, causes decreased carbon dioxide tension of the alveolar air and blood, and a reduction of the fixed alkali in the blood by the excretion of an alkaline urine. Also it is their contention that for this reason the administration of alkali is contraindicated in the treatment of salicylate poisoning, in contrast to the view of others. Johnson¹² found that four of eight of his experimental cats which had received the equivalent of a full therapeutic dose of sodium salicylate had significant decreases in the alkali reserve and that in these there was an increase in blood lactate. He believes that these changes are reconcilable with a fixed acid acidosis.

The literature on salicylate poisoning has been reviewed by other authors prior to 1928. Space here does not permit us to consider them comprehensively. A comparative list of the changes in diabetic coma and salicylate poisoning based on our review is presented in table form. During this period reports of thirty-two severe cases were found. In fifteen the salicylate was administered therapeutically, in eleven either by accident, self administration or error, and in four deliberately for the purpose of self destruction. One

followed the use of salicylate injection into varicose veins. Death occurred in one half of the cases. Twenty-five of the cases occurred outside the United States.

A considerable number of cases have come to necropsy and while the pathologic changes are not sufficiently characteristic to permit the pathologist to make an unequivocal diagnosis of salicylate poisoning in the absence of a history or the demonstration of large amounts of salicylate in the body fluids, nevertheless certain changes warrant such a suspicion. Madisson⁶ found an engorgement of the blood vessels of most of the organs with small hemorrhages in both human and experimental (rabbits) salicylate poisoning, also cloudy swelling of the heart, liver and kidneys, which in some instances had progressed to fatty degeneration. Inci-

Comparative Conditions Found in Diabetic Acidosis and Salicylate Poisoning*

dently, he believed that his experiments showed that the administration of dextrose along with the salicylate lessened the intensity of the reaction and delayed death.

CONCLUSIONS

1 Salicylate poisoning appears to be a clear clinical entity, but one that may be confused with diabetic or renal acidosis.

2 Salicylate poisoning should be considered when one is eliminating the various causes of coma, especially if hyperpnea is present.

3 The finding of the violet color reaction in the spinal fluid with ferric chloride may be a useful differential diagnostic procedure, it would have been in our case.

4 Physicians should be acquainted with the syndrome produced by the overdosage of salicylate, especially since the drug is so widely used, in its various forms, as a therapeutic agent, a household remedy, and a method of suicide.

5 The dyspnea of salicylate poisoning appears to be more reasonably explained on the basis of an irritative action on the respiratory center than on acidosis.

Clinical Notes, Suggestions and New Instruments

FAILURE OF SODIUM CHLORIDE RESTRICTION TO PRECIPITATE CRISIS IN A CASE OF ADDISON'S DISEASE

RICHARD M. JOHNSON, M.D., MINNEAPOLIS

Many of the symptoms of adrenal insufficiency are those commonly associated with dehydration and depletion of the bases of the animal body, chiefly sodium. In cases of Addison's disease the administration of an adequate amount of sodium tends to produce a more nearly normal state of hydration and corrects the sodium deficit. Harrop¹ first suggested that sodium chloride restriction precipitated crises in patients suffering from Addison's disease and could be used in this manner to establish a diagnosis in questionable cases. The following case is presented as evidence that such a test is not reliable in all instances.

REPORT OF CASE

History—Mrs. E. W., aged 39, admitted to the medical service of Dr. H. A. Reimann at the University Hospitals in July 1934, gave the following history. She had not been strong since she suffered from "milk leg" following the birth of her last living child in 1920. In 1928, during the ninth month of gestation, a severe painless vaginal hemorrhage developed following which she delivered a dead full-term fetus. Thereafter she experienced a greater sense of fatigue and a reduced ability to work. In December 1933 the patient noticed puffiness of the eyelids and general body surface, nausea, vomiting and

Blood and Urinary Dextrose Values

pallor, and experienced an attack of syncope with loss of consciousness lasting about eight hours. She remained in bed at home for three or four weeks and in January 1934 was transferred to a hospital, where she had a second attack of syncope and unconsciousness, which lasted for several hours and was said to have been rather dramatically relieved by the intravenous administration of a dextrose solution. The patient was later able to do some housework but experienced spells of dizziness and marked weakness. A few weeks prior to admission thyroid extract was prescribed, and following this puffiness of the eyelids and subcutaneous tissue disappeared, but other symptoms were not changed.

The patient was well developed, with evidence of recent loss of subcutaneous tissue. There was questionable pigmentation in the skin folds of the palms of the hands and soles of the feet and around the umbilicus, but no abnormal pigmentation was noted in the mucosa of the mouth, pharynx or eye fundi. No significant finding was observed when the head, neck, chest, abdomen, genitalia and extremities were examined. The heart tones were somewhat faint but otherwise normal. The blood pressure on admission was 88 mm systolic and 60 mm diastolic.

Laboratory Examinations—Several urinalyses were negative. The hemoglobin averaged 75 per cent (Sahli), there were 3,100,000 erythrocytes and 5,000 leukocytes per cubic millimeter of blood, 48 per cent of which were polymorphonuclear granulocytes, 51 per cent lymphocytes and 1 per cent eosinophils. The nonprotein nitrogen of the blood measured 26.2 mg per hundred cubic centimeters. Blood Wassermann tests were negative. The blood and urinary dextrose values following the intravenous injection of 40 Gm of dextrose are given in the accompanying table. Five basal metabolic rates varied from minus 20 per cent to minus 30 per cent. The carbon dioxide

combining power of the blood was 64 volumes per cent. The blood plasma contained 600 mg per hundred cubic centimeters of chlorides. The stools were normal.

Course—The patient was at first thought to have Addison's disease. A Mantoux test with 0.1 mg old tuberculin was strongly positive. X-ray plates of the lungs, heart, kidneys and adrenals failed to show any evidence of abnormality. The patient was given 3 grains (0.2 Gm) of desiccated thyroid daily for about one month without definite improvement. This medication was discontinued and she was given 9 Gm of sodium chloride daily in addition to the general hospital diet. After one week the patient stated that she felt better than she had in a long time. She was then given a diet low in sodium chloride (approximately 15 Gm daily) from September 4 to September 25. This twenty-one day period of sodium chloride restriction did not cause recurrence of symptoms. The chloride and nonprotein nitrogen content of the blood were not altered. The blood pressure varied but little, averaging 90 mm systolic and 65 mm diastolic.

Hypothyroidism was then considered as the most probable diagnosis, and the patient was discharged with instructions to follow a high caloric general diet and take 1 grain (0.06 Gm) of desiccated thyroid (Armour's) three times daily. She was readmitted one week later, October 1, because of headache, persistent vomiting and great fatigue. The physical changes were essentially the same as those previously described, except that the patient was slightly dehydrated. Laboratory examination on the second admission showed that the hemoglobin had dropped from 75 per cent to 55 per cent and the erythrocytes from 3,500,000 to 2,700,000 per cubic millimeter. The nonprotein nitrogen content of the blood increased from 26.2 to 33.3 mg per hundred cubic centimeters. The blood pressure varied from 76 to 88 mm systolic and 52 to 60 mm diastolic. The patient was given dextrose solution and physiologic solution of sodium chloride intravenously with great improvement in her general condition. She appeared to improve gradually but died very suddenly and unexpectedly with gasping respiration and obvious air hunger.

A complete autopsy was performed. The only abnormal conditions found were bilateral hydrothorax of approximately 100 cc of clear straw-colored fluid. Both adrenals were so atrophied that they could be identified only on microscopic examination, which showed an extreme atrophy of the cells of the cortices with condensation of the supporting connective tissue stroma. The medulla was represented by a few widely distributed small groups of characteristic cells, a considerable number of which showed pyknotic nuclei with lipid vacuoles in the cytoplasm. There was no evidence of inflammatory reaction. The thyroid gland was small. The cut surface was pale and the microscopic sections showed a decrease in colloid and acini. The cells lining the acini were flat, and there was considerable lymphocytic infiltration of the stroma. The ovaries were pale, small and hard. On microscopic examination no graafian follicles were found in the several sections examined. A few corpora albicantia were present.

The diagnosis was Addison's disease, bilateral cortical atrophy, hypothyroidism, chronic thyroiditis, bilateral hydrothorax, and atrophic ovaries.

COMMENT

Clinically this case was considered an example of hypothyroidism rather than Addison's disease because of the edema or myxedema of the subcutaneous tissues, the low basal metabolic rates, the absence of definite pigmentation, and the failure of sodium chloride restriction to precipitate an addisonian crisis. However, the postmortem examination revealed a marked atrophy of both adrenals in addition to a chronic thyroiditis. The adrenal insufficiency was in all probability the cause of the patient's sudden death. Bilateral adrenal cortical atrophy is not uncommonly the cause of Addison's disease but in our experience the absence of characteristic pigmentation in bilateral cortical atrophy is rare. The failure of sodium chloride restriction to precipitate a crisis in this case may be explained by the presence of an adequate amount of adrenal hormone at that time to prevent excessive sodium excretion and the associated dehydration. others have shown that there is a decreased sodium chloride excretion in hypothyroidism and that, when the hypothyroid state is corrected by feeding of thyroid or injection of thyroxine, the excretion of sodium chloride increases. This patient received thyroid extract before the period of sodium chloride restriction but not sufficient to increase the basal metabolic rate above minus 20 per cent, consequently the sodium chloride excretion was probably low. During the period prior to salt restriction the patient received 9 Gm of sodium chloride daily, which may have resulted in sodium chloride retention, and because of the hypothyroidism the subsequent twenty one day period of restriction was too short to deplete the patient's supply of sodium chloride. Wilder⁴ has been able to induce crises in Addison's disease by high potassium feeding. This suggests that potassium may exert an influence opposite or antagonistic to that of sodium in Addison's disease similar to that observed in certain juvenile diabetic patients and in patients with tissue edema. It is possible that the adrenal cortical hormone is an important factor in the control of the sodium-potassium ratio in the body.

MIGRATING GRÄFENBERG CONTRACEPTION RING

C J ANDREWS M.D. NORFOLK VA

It appears that the use of a flexible metal ring in the uterus as a contraceptive is rather widespread, and according to an advertisement in a medical journal the manufacturers advise that it is both efficient and safe. This apparatus is variously called Von Graffe ring, Gomco contraception ring and Gräfenberg ring. A foreign body remaining in the uterus would be expected to give some unfortunate results.

The case which I report is one of these. I have found very little in the medical literature on this subject, but I have collected the reports of three other cases which would further suggest the danger of the use of such an apparatus.

Jan 14 1936, Mrs. X consulted me. Her last period began Oct 5, 1935. She told me that a contraceptive ring had been inserted in the uterus in November 1934, and she brought with her a roentgenogram taken eight months before which showed the shadow of a ring apparently near the center of the pelvis. The uterus was about the size of a three months pregnancy. She told me that the ring had been inserted by a prominent gynecologist in another city. As I was not familiar with this particular instrument, I wrote to him for information. He courteously reported that he had placed a Von Graffe ring (apparently a Gräfenberg ring) in November 1934. He also said that these rings had been used in Germany in many thousand cases and that pregnancy could be expected in only about 1 per cent of the cases, but that if it did occur an abortion would be required, as the child would be deformed.

Obviously if the uterus was to be emptied it was necessary that the ring also be removed to prevent complications. Another picture was made, which showed the ring in about the same location as before. As the patient was now about four months pregnant, hysterotomy seemed to meet the indications best. The contents of the uterus were evacuated but no ring could be found. Grasping the cervix between the thumb and the fingers, I felt the ring in the wall of the cervix. On further investigation the edge of the ring was seen under the bladder flap of peritoneum. It was divided and removed. A part of the ring was embedded in the wall of the cervix. If I had found this first I would not have opened the uterus.

Cregan¹ reports a conception with the Gräfenberg ring in place. This resulted in spontaneous abortion associated with streptococcal septicemia incidental to middle ear infection.

Green-Armytage² reports an infected abortion of nine weeks gestation. The Gräfenberg ring was found embedded in the chorion.

Murphy³ describes a case of three months pregnancy complicated by a migratory Gräfenberg ring. The chief complaint was pelvic pain particularly on walking and a sick feeling. Roentgen examination showed the ring apparently to one side

of the uterus. When the abdomen was opened, the ring was visible showing through the peritoneum of the broad ligament. It was divided and removed and pregnancy was allowed to proceed.

Including the three cases found in the literature, four cases of pregnancy are here reported in which the Gräfenberg ring failed to prevent conception. In two of these the pregnancy ended in septic abortion, and in two the ring migrated out of the uterus, requiring abdominal operation.

It is possible that other such results have followed. This information may serve to curb some enthusiasm as to its efficiency and safety.

THYROTOXICOSIS

CLINICAL LECTURE AT KANSAS CITY SESSION

THE RT HON LORD HORDER, KCVO, MD,
F.R.C.P.

Consulting Physician St Bartholomew Hospital
LONDON, ENGLAND

May I preface my address by telling you how greatly I appreciate the honor and privilege of attending these Kansas City meetings of your Association. The subject on which I am speaking was suggested by those responsible for my name being on the program, but it would be ungracious of me to hold them responsible for what I say. And yet I do not think they need fear even if I did, because I have nothing of an iconoclastic nature to say. What intelligent person has in a field where exact knowledge is so meager? The temptation to exceed the facts, though great, must be resisted. I have no new facts to offer you, but if I can clear the air a little by a reminder of what we know, and what we only presume, that may be a contribution not altogether worthless and—or so I think—not untimely.

Take this word "thyrotoxicosis," for example. I am uncertain that it serves any very useful purpose. Anyway, unless it is taken in the most generic sense to connote all the toxic states in which there is a thyroid factor concerned—whether the thyroid is the sinner or is more sinned against than sinning, and whether the gland is disturbed only in a functional sense or is the seat of gross organic disease—only in this way should physicians tolerate its introduction into the nomenclature. The question arises whether if this principle is acknowledged, the word can really be justified. But it has arrived, and the best thing we can do is to watch it, and to see that it does not mesmerize us into the belief that its arrival has taught us a new fact or series of facts.

It would be an interesting digression to consider how the premature introduction of new words and phrases can obstruct, rather than help, the progress of medicine. But I must refrain, at least this morning. But I do not think it amiss to remind you that Thomas Hobbes, the father of English philosophy, warned us that "words are the counters of wise men but the monies of fools." In no study is it more imperative than in medicine that we should heed his warning.

The great objection to the word "thyrotoxicosis" is that it postulates a basic fact which has never been established. There is no indisputable evidence that exophthalmic goiter owes its evolution in the main, or

even in a lesser degree, to the circulation of disordered thyroid secretion. The same may be said of the symptoms variously classified under the terms "toxic goiter," "toxic adenoma." *Pace* certain textbooks whose authors or editors strive prematurely to substitute for non-committal names of diseases terms having precise pathologic connotation, the postulate that exophthalmic goiter is an expression of mere hyperthyroidism is even less authenticated, whether on clinical or on experimental grounds.

Until we find some method of measuring the amount of thyroid secretion poured out into the blood stream—and at present we possess no such method—we shall not solve the main problem facing us in this matter.

There are facts which suggest that the thyroid hyperplasia which is the characteristic change in the fully developed picture of exophthalmic goiter is not the primary, but a secondary, phenomenon. Certainly there is no quantitative relation between the degree of thyroid enlargement and the degree or the duration of the symptoms. The latter may be very severe and active in association with very little, or even with no thyroid enlargement, but again the symptoms may be mild and tending to quiescence in association with considerable hyperplasia. Nor is there any reason to believe that we have yet established any qualitative relation by which I mean that there is no evidence that the secretion from gland tissue that is merely hyperplastic diffusely fibrotic or the seat of adenomas differs from that which is elaborated by a healthy gland. Nor, again (to complete the series of morbid anatomic changes in the thyroid which appear to have associations with metabolic increase and/or with sympathomimetic manifestations), is there evidence that the cells of an adenoma themselves yield a pathologic secretion.

DEVELOPMENT OF THE DISEASE

In considering the pathogenesis of exophthalmic goiter the use of the term "thyrotoxicosis," as already noted, lands us at the very center of the problem. What is the *causa causans*? It remains hidden. As in so many other instances, nature has revealed the results of a disease process but jealously guards the secret of the exact mechanism by which these results are evolved. We see the picture on the screen quite plainly but the projector is hidden. That some poison is at work seems an irresistible conclusion. Especially suggestive in this connection are the crises often pyrexial which are so alarming a feature and prognostically so serious. They surely give us a dramatic presentation of an intense toxemia. There is no reason for believing them to be of microbic origin. Are they metabolic? Or are they due to the flooding of the circulation by some uncontrolled physiologic hormone? What part in the pathogenesis of the disease is taken by iodine metabolism?

The removal of a large part of the thyroid gland in a chronic and established case of the disease, resulting, as it often does in such a marked subsidence of the symptoms, suggests that the source of manufacture of the poison resides in the gland. But the actual proof of this hypothesis eludes us despite painstaking research. Moreover we must exercise great care in the argument at this point. Thyroidectomy may interrupt a vicious circle in the patient's interest and so do good in quite another fashion than by getting rid of the primary cause of the trouble. There are analogies bearing on this possibility: splenectomy in splenic anemia and the same operation in acholuric jaundice. It is feasible that the missing clue may be

found extrinsic to the thyroid. Indeed such a possibility is coming to be regarded as probable. But it may be found to be extrinsic to the involuntary nervous system also, though it certainly appears as if the latter organ bulks largely in, at any rate, the earlier stages of the disease. Biochemistry linked with histology may find the solution, for here is a field of discovery of enormous potential value, as we appreciate when we realize the unveiling by these methods of the reticulo-endothelial system, and its bearing on the mechanism of addisonian anemia.

Of the state of the thyroid gland itself, quite apart from the moot question of the exact relation which it bears to the syndrome in general I do not propose to deal in detail. The fact that so many different pathologic conditions may be present in association with the syndrome I am considering has induced some workers to discard the thyroid altogether as being even indirectly concerned in a causative sense. Yet the conclusion that the gland is intimately bound up with the pathogenesis of exophthalmic goiter seems, on clinical grounds, indisputable. But the factor of metabolic increase has by some been discarded also. Indeed, certain of the recent analyses of this baffling syndrome remind me not a little of the devastating and uneconomical criticism of the cynical friend who gradually reduced the fishmonger's caption "Fresh Fish Sold Here" to no caption at all by the elimination of unnecessary words. There was no need for the word "fresh," he said, for surely he wouldn't sell stale fish, no need for the word "here," since his shop wasn't anywhere else, no need for the word "sold," because he didn't give the fish away, and no need for the word "fish" for it could be smelled two streets off. The exophthalmos may be only a symptom, the thyroid gland may be secondarily and not primarily affected, the involuntary nervous system may be stimulated from without and not from within and the basal metabolic rate may be low rather than high. But the subtleties of too fine an analysis confuse, rather than clarify, our ideas seeing that the basic data are as yet so meager. The stubborn fact remains. Exophthalmic goiter exists for all to see. The syndrome repeats itself with increasing persistence and demands our attention. If we take our stand here we are on the sure ground of clinical medicine, and in my further remarks this is what I propose to do.

ETIOLOGIC FACTORS, SYMPTOMS AND COURSE

The known etiologic factors, the symptoms and the course of the disease call for a few remarks. That there is a diathesis in exophthalmic goiter is generally accepted. But whether the flaw resides in the involuntary nervous system or in the psyche or in the endocrine balance, or in some other as yet unrecognized tissue or function, or in more than one of these we do not know. Of the predisposing causes we know a little: sex, certain collateral familial conditions and an "autonomic imbalance." Of exciting causes there are the sex epochs, there are psychic traumas, and there is focal sepsis. Or is it merely fashion which leads us to speak of focal sepsis? For myself, I have been very disappointed in the search for focal sepsis in exophthalmic goiter, however thorough this search may have been. Associated endocrine defects are sometimes advanced as a contributory cause but the evidence is entirely unconvincing. Is this mere fashion again? Or is the suggestion due to a desire to give support to the hypothesis that exophthalmic goiter is itself an endocrine disorder? Of this however, there is as already remarked, no good evidence.

To the original three symptoms observed by Graves—the exophthalmos, the tachycardia and the goiter—Charcot added tremor. These constitute the cardinal features. Many others have been noted from time to time, among them various ocular changes, dermatoses, glycosuria, neuroses, psychoses, and manifestations of sympathetic instability such as flushing, sweating and diarrhea. Loss of weight is very common, though, as in diabetes, which is one of the familial associations, the patient may be fat rather than lean. Lesser degrees of the disease are recognizable, and, given favorable conditions, these quite frequently abort.

An attempt has been made by some to segregate cases which present some of, or even all, the symptoms of exophthalmic goiter but which show no increase in the basal metabolic rate—a striking feature in the great majority of the established cases. It is proposed to use the term “autonomic imbalance” for these cases in which the basal metabolic rate is not raised. How far this segregation is justified, and what proportion of these cases pass on to what these observers would call true exophthalmic goiter, we do not yet know. Granted that the basal metabolic rate, as a measure of metabolic activity, is of fundamental importance, too much weight must not be attached to this criterion. The basal metabolic rate is raised in some conditions which are not, and do not tend to become, exophthalmic goiter. On the other hand, some cases of exophthalmic goiter, if we use the clinical standard occur with a normal, or even lowered, basal metabolic rate.

As regards the course of the disease, in the majority of cases the onset and the early stages are insidious. In a few cases the origin seems to be acute or even abrupt, but here, as in some other diseases, such as diabetes and disseminate sclerosis, it is usually possible to trace a latent stage of the disease before the exacerbation arrives. When fully developed, and even when the patient is very ill indeed, the disease may subside completely and with no recognizable residues—a very striking experience. Or the established picture may remain long enough to render organic residues permanent, even though quiescence arrives. But, unfortunately, in a large proportion of the established cases the fire even if it dies down somewhat, continues to smolder. The patient becomes a chronic invalid, with at first functional and intermittent, and, later, organic and permanent heart damage. In still other cases the fire, instead of dying out or dying down, blazes and the patient succumbs to an intense and overwhelming toxæmia, the so-called thyroid crisis.

DIAGNOSIS

The diagnosis of exophthalmic goiter may be very easy or it may be very difficult. The difficulty lies in a recognition of the early and the incomplete pictures. It is these which call for clinical acumen, and it is these which reward the observer so abundantly if he discovers them. The secret if secret there be, lies in bearing the disease in mind when one is faced with an obscure case having nervous or metabolic features. Training in the observation of facies and behavior is of paramount importance. Whenever these deviate from the average we should not rest until we have a positive, not merely a negative, explanation. The formula ‘I failed to elicit any signs of organic disease’ and the supposed comfort to be derived from it have hidden many an early case of exophthalmic goiter and will continue to do so for years to come. In these days we tend to fall upon a patient too early after our first contact with him so anxious are we to pass him through

the mill of our routine examination of his various organs. Exophthalmic goiter in its early stages is a disease of the patient and not of her organs. So let us give ourselves time ‘to stand and stare’ as the poet has it. We shall then have a chance of observing if the patient is staring, and why. Be it observed that the “stare” is not merely, or perhaps not at all, a matter of exophthalmos: there are the enlarged palpebral fissures, the infrequency of blinking, the dilated pupils and the immobile forehead. But there is also the manner of entering the room, the hot hand, quickly given and quickly withdrawn, the restlessness, the rapidity of movement, the lack of poise, the excess of gesture, the record short time spent in undressing and in dressing, the moist skin, and the flush on the neck and chest.

Unexplained loss of weight, especially in men who are past middle age, should always raise the question of exophthalmic goiter. So also should certain changes in the patient's conduct, whether noticed by others or—and this sometimes happens in highly conscientious and self-critical women—by the patient herself: unwonted lack of control, irascibility, excessive show of the emotions, and the quick expenditure of an unaccustomed store of nervous energy without apparent fatigue.

TREATMENT

In considering the treatment of exophthalmic goiter the physician must concern himself with prevention whenever the diathesis is recognized: a thankless task, for, as a philosopher has truly observed, it is not to be expected that human beings will accept advice when they will not accept warning. And the fact that the potential victim of the disease is more often a woman than a man lessens the chance of much being accomplished in this direction.

The picture of the slighter manifestations of the sympathomimetic part of the syndrome—to use Dale and Barger's term—too often escapes detection, as already remarked. Yet if these “larval” types, or “formes frustes,” are noted, the physician has a better chance than if committal symptoms have declared themselves. Even so, his efforts seldom carry conviction. To some his suggestions savor too much of washing in Jordan, to others they constitute an intolerable interference with that round of excitement which entails so much psychologic and nervous stress for many young people. The doctor is often accused of wanting to make his patient a cabbage. Yet for those who accept his control and cooperate with him there is undoubtedly a good promise of stabilization. The chief difficulty, next to the temperament of the patient, lies in securing the necessary relief for those who are forced by their economic position to earn their daily bread by jobs which make excessive demands on their nervous system. Whenever possible—and this applies to all classes—the question of the patient's occupation should be carefully considered. Though it is not necessary that the patient should become a cabbage in order to attain physiologic salvation, it may help him very materially to grow cabbages, or something equally useful. The more rustic the type of routine, the better, it is no mere shibboleth that leads the doctor to preach the doctrine of “the simple life” to these patients.

If the symptoms persist in spite of controlling the patient's routine of life, and in all cases in which the full syndrome has developed, the degree of physiologic and psychic rest should be absolute and should be continued for at least three months. Bed is the only place where such rest can be guaranteed. A good deal of time can be wasted over compromises for the adoption

of which most patients seek to win their doctor's sanction. To yield or not to yield is the test of the latter's experience of the disease. To secure rest of the mind, a heart-to-heart talk of an entirely confidential nature is imperative, and it is best to assume the existence of some emotional hold-up, since this is so frequently present. The patient should be given confidence in her ability to get well, though the need for patience should not be concealed. It is better to discount anything by way of a royal road from the first.

If focal sepsis is present, this should be eliminated as far as possible. Efforts at specific therapy based on the hypothesis of the thyroid dysfunction, whether by the use of serum from thyroidectomized animals or from animals inoculated with excess of thyroid secretion, have failed in the hands of most observers. There is no specific drug, though there are drugs that help iodine certainly, and in all cases in which the thyroid is involved (but surely there is room for more research into the best methods of exploiting this drug to its best advantage), belladonna (introduced by Trousseau) in some, the bromides in others. Of quinine hydrobromide, which has had a vogue, I cannot myself give any good account. Digitalis appears to be unhelpful apart from cardiac dilatation.

There remains the important question of partial thyroidectomy, a form of treatment which has so far justified itself of late years that debate on the main issue seems unnecessary. In what cases, therefore, and especially how, it behoves us very carefully to consider. Suffice it to say that in my own experience the operation should be undertaken whenever the disease remains active after six months of carefully supervised medical treatment, and also in cases which relapse in spite of the patient's routine of life being adequately controlled. I agree, too, that the operation is indicated in all cases in which auricular fibrillation has developed, and that it is indicated still more absolutely when signs of congestive heart failure are present, whether the cardiac rhythm be so affected or not. To delay when any of these three criteria have arrived is to lose valuable time and to lessen the benefit which may otherwise be expected. I do not propose to consider the technic. But no doubt we should all desire that the procedure be as bloodless as possible, that every patient be allowed the benefit of her parathyroids, that the recurrent laryngeal nerves be left intact, and that as few cases of myxedema be created as may be.

As for the question of an immediate mortality, the difference between a patient being only chronically ill one day and very dead the next is so tragic and so striking—an experience that was not very uncommon until a few years ago—that it is a relief to know that this difference can be eliminated by careful preparation for the operation by skilled technic in its performance and by a form of anesthesia which is competently chosen and as competently administered.

It is not without significance that the most striking results of thyroidectomy are seen in those cases which are advanced and in which the vicious circle is complete. Always provided the load of the procedure is not more than the patient can carry. One conclusion that may be derived from this fact and the general results of the procedure is that if you want to do the operation of subtotal thyroidectomy in exophthalmic goiter, a disservice you will do it too early.

We must consider whether the known benefits seen after ablation of the thyroid in some cases of congestive heart failure throw light on the rationale of

subtotal thyroidectomy in exophthalmic goiter. We must not omit to remember, in this connection, the fact that surgeons tend to remove more and more of the gland, whether in one or two stages, and that some of them attribute to this change in stratagem and in the tactics involved the better results seen today as compared with those seen formerly. That I discuss the question of surgical treatment even as much as I do is because I believe that if we can properly assess the criteria and the responses connected with this important procedure, we shall make a valuable contribution to the elucidation of what is at present a great mystery—the pathogenesis of exophthalmic goiter.

I understand that those who have studied most fully the results of total thyroidectomy in congestive heart failure have quite recently come to the conclusion that, despite the striking immediate effect on the decompensation and on associated anginous symptoms, the procedure is, in the majority of cases, scarcely worth the patient's while. But the adventure may be said at least to have taught us something, and this is, after all, a not uncommon result in surgical adventures—medicine gains more than the patient. Just as it takes all sorts of people to make up a world, so it takes all sorts of experimental measures, those that are retained as serviceable, as well as those that are discarded ultimately to make up a system of effective therapy in obscure disease processes.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS FORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

KEPHRINE HYDROCHLORIDE—Methylaminoacetate catechol hydrochloride— α -keto β methylamine-ortho para dihydroxyethyl-benzene hydrochloride— $(\text{OH})_2 \cdot \text{C}_6\text{H}_3 \cdot \text{COCH}_2 \cdot \text{NH}(\text{CH}_3) \cdot \text{HCl}$. Kephrene hydrochloride is the monohydrochloride of a base resembling epinephrine (lacro-methylaminoethanol catechol) but differs in that kephrene possesses a ketone group in place of the secondary alcohol group of epinephrine.

Actions and Uses—Kephrene hydrochloride acts by constriction of the blood vessels. In comparison with epinephrine its action is less powerful, but the effects are more lasting. Kephrene hydrochloride is used only locally and will, as a rule, arrest capillary bleeding within two or three minutes. The hemostatic effects usually persist from one to two hours. As there is no appreciable absorption of kephrene hydrochloride into the blood stream, it does not have any noticeable effect on the blood pressure. Kephrene hydrochloride is not destroyed by blood alkali.

Dosage—Kephrene hydrochloride is marketed in the form of powder and suppositories, bandages and gauze impregnated with kephrene hydrochloride are also supplied. The selection of a suitable dosage form is governed by the anatomic or pathologic characteristics of the individual case.

Manufactured by Pharmazeutische Industrie A. G. Vienna, Austria (Campbell Products Inc., New York, distributor). No U. S. patent or trademark.

Kephrene Hydrochloride Powder—Kephrene hydrochloride 5 parts and tricalcium phosphate 95 parts.

Kephrene Hydrochloride Rectal Suppositories—Kephrene hydrochloride 3 parts, extract of belladonna 1 part in 96 parts of a suppository base.

Kephrene Hydrochloride Bandage—Bandages 5 meters long and 1, 1.5 and 8 centimeters wide, impregnated with kephrene hydrochloride 1 Gm. per 3,000 square centimeters.

Kephrene Hydrochloride Gauze—Gauze impregnated with kephrene hydrochloride 1 Gm. per 3,000 square centimeters.

Kephrene hydrochloride occurs as a white, odorless powder, freely soluble in water, soluble in alcohol, insoluble in ether. Its aqueous solution is neutral to litmus. Kephrene hydrochloride melts with decomposition at 238 to 240°C. It is soluble in 0.5 Gm. of kephrene hydrochloride in 25 cc. of water and a very light excess of ammonia water or 1 cc. of

resultant methylaminoacetatechol on a filter paper, wash and dry at 100 C a yellow crystalline powder results which on heating deepens in color at 200 C and melts with decomposition at 230 C the filtrate from the foregoing gives a white precipitate with silver nitrate solution insoluble in boiling nitric acid but soluble in an excess of ammonia water

Dissolve about 0.02 Gm of kephrine hydrochloride in 20 cc of water, separate portions of 2 cc yield a canary yellow color with 1 cc of ammonium molybdate solution which is not discharged on subsequent addition of 0.3 cc of dekanormal sodium hydroxide solution (distinction from epinephrine), a bluish purple color with 0.2 cc of a 1:100 sodium nitroprusside solution, 1 cc of sodium hydroxide solution and 0.2 cc of glacial acetic acid (distinction from salts of ephedrine, neosynephrine and tyramine). Boil about 0.01 Gm of kephrine hydrochloride with 2 cc of alcoholic potassium hydroxide solution and 3 drops of chloroform no odor of phenylisocyanide is evolved (primary amines). To about 0.1 Gm of kephrine hydrochloride to 5 cc of water add 1 cc diluted hydrochloric acid and 1 cc. of barium chloride solution no turbidity develops (sulfate).

Dry about 0.5 Gm of kephrine hydrochloride accurately weighed to constant weight at 100 C, the loss does not exceed 7 per cent. Incinerate about 0.5 Gm of kephrine hydrochloride accurately weighed the residue is not more than 0.1 per cent. Transfer about 0.25 Gm. of kephrine hydrochloride accurately weighed to a 500 cc Kjeldahl flask and determine the nitrogen content according to the method described in Methods of Analysis of the Association of Official Agricultural Chemists third edition, page 20 art. 22 the amount of nitrogen is not less than 6.35 per cent nor more than 6.5 per cent when calculated to the dried substance. Transfer about 0.3 Gm. of kephrine hydrochloride accurately weighed, to a suitable Erlenmeyer flask, add 100 cc of water, previously boiled to remove carbon dioxide and titrate with tenth normal sodium hydroxide solution using phenolphthalein as an indicator the amount of hydrogen chloride found corresponds to not less than 16.5 per cent nor more than 17 per cent, calculated to the dried substance. Transfer about 0.3 Gm. of kephrine hydrochloride accurately weighed to a suitable glass stoppered Erlenmeyer flask, dissolve in about 20 cc of water neutralize with a diluted ammonium hydroxide solution, adding a very slight excess place the flask and contents in a refrigerator at 5 C, and allow to stand for eighteen hours. Collect the precipitate on a tared Gooch crucible wash with cold water followed by cold alcohol and ether, dry to constant weight at 100 C. the percentage of methylaminoacetatechol obtained corresponds to not less than 83 per cent, nor more than 86 per cent calculated to the dried substance.

KINNEY'S COD LIVER OIL CONCENTRATE LIQUID—A concentrate of the unsaponifiable fraction of cod liver oil dissolved in sufficient cod liver oil to give the desired potency to the marketed product. It has a vitamin A potency of not less than 60,000 units (U S P) per gram and a vitamin D potency of not less than 8,500 units (U S P) per gram

Actions and Uses—It possesses the therapeutic properties attributed to the vitamins present in cod liver oil

Dosage—For the Liquid Infants, from six to eight drops daily, children, two to four drops three times daily adults, four drops three times daily. The liquid is marketed with a dropper designed to supply $\frac{2}{3}$ minim (0.041 cc.) in each two drops. For the Capsules Children, one capsule daily, adults, one to two capsules daily

Manufactured by the Health Products Corporation, Newark N J (Scientific Sugars Co. Indianapolis distributor) U S patent 1984 858

Kinney's Cod Liver Oil Concentrate Capsules 3 minims—Each capsule contains Kinney's Cod Liver Oil Concentrate Liquid, 3 minims and has a vitamin A potency of not less than 10,000 units (U S P) and a vitamin D potency of not less than 1,450 units (U S P)

Kinney's Cod Liver Oil Concentrate Liquid, Vials 5 cc—Each $\frac{2}{3}$ minim (0.038 Gm) has a vitamin A potency of not less than 2,280 units (U S P) and a vitamin D potency of not less than 320 units (U S P)

DIPHTHERIA IMMUNITY TEST (SCHICK TEST) (See New and Nonofficial Remedies, 1935, p 408)

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

Diphtheria Toxin for Schick Test Diluted Ready for Use Mulford—A diphtheria toxin diluted with a sodium chloride-borax-boric acid buffer solution containing 0.1 per cent of Witte's peptone, so that 0.1 cc contains a Schick test dose ($\frac{1}{50}$ minimum lethal dose). The minimum lethal dose is determined by injection of graduated doses into a series of 250 Gm guinea pigs. Marketed in 1 cc vials containing sufficient material for ten tests in 5 cc vials containing sufficient material for fifty tests and in 10 cc vials containing sufficient material for one hundred tests. For the control test a diluted diphtheria toxin inactivated by heat is supplied in 5 cc vials representing sufficient material for fifty control tests.

INSULIN (See New and Nonofficial Remedies, 1935, p 227)

Insulin-Mulford (See New and Nonofficial Remedies, 1935, p 231)

The following dosage form has been accepted

Insulin Mulford 100 units 10 cc Each cubic centimeter contains 100 units

ALLERGENIC EXTRACTS-LEDERLE (See New and Nonofficial Remedies, 1935, p 28, THE JOURNAL, July 11, 1936, p 130)

The following additional product has been accepted

Alfalfa Allergenic Extract Lederle

LIBBY'S BRAND CALIFORNIA ORANGE JUICE

Manufacturer—Libby, McNeill & Libby, Chicago

Description—Canned California orange juice retaining in high degree the original vitamin C content

Manufacture—Tree-ripened Valencia oranges are sorted, scrubbed with water, halved and the juice and pulp mechanically burred out. The juice is vacuumized, filled into cans which are closed under vacuum, processed in agitated cookers and immediately cooled. The entire process requires only a few minutes

Analysis (submitted by manufacturer) —

Vitamins—Chemical titration shows an average cevitic acid (ascorbic acid) content of 0.6 mg per cubic centimeter, 174 mg per fluidounce, as compared to 0.7 mg per cubic centimeter for fresh juice, showing practically no reduction of vitamin C in canning

Claims of Manufacturer—This orange juice is practically equivalent to fresh juice in nutritive value. For all dietary and table uses

ARIZ-SWEET BRAND GRAPEFRUIT JUICE (SUGAR ADDED)

Manufacturer—Ariz-Sweet Grapefruit Growers, Ltd, Peoria, Ariz

Description—Canned Arizona grapefruit juice, with added sucrose, retaining in high degree the original vitamin C content

Manufacture—Same as Ariz-Sweet Brand Grapefruit Juice, (THE JOURNAL, April 25, 1936, p 1474), except that a small amount of sugar is added.

Analysis (submitted by manufacturer) —

SATURDAY, JULY 25, 1936

A CLINICAL STUDY OF ABORTION

A steady increase in admissions of abortions in some hospitals in England has occurred during the last ten years. Indeed, about 2 per cent of the total admissions in the general hospitals of the London County Council are cases of abortion. The deaths attributed to abortion in England and Wales in 1933 amounted to 24.2 per cent of the total deaths from puerperal sepsis.

In his recent review of 1,000 cases of abortion, Parish¹ found that 203 of the women had no living children and 173 were pregnant for the first time, 207 of these women had one living child and only 136 had six or more children. Admittedly, 485 of the women had induced abortion by one means or another, varying from the employment of an abortionist to the use of slippery elm bark. Most of the deaths that occurred in the entire series were in this group. In another group, of 246 cases, abortion was the result of various diseases or conditions, the most common, in order, being uterine displacement, accidents, pulmonary diseases, pelvic diseases, lacerated cervix and renal diseases. There was no intervention in this group, and there were no deaths. Of the 1,000 cases under review, infection was present in 48.3 per cent on admission to the hospital.

For the group of 151 cases of threatened abortion, the plan of treatment was to place the patients completely at rest, giving 0.016 Gm (one-fourth grain) of morphine if pains were present, and to defer pelvic examination if the diagnosis was clear. With this treatment 57 per cent of the patients with threatened abortion were discharged still pregnant. For the 148 cases of inevitable abortion, no treatment other than ergot was given unless there was a special indication. If the abortion was not progressing, an enema was given followed by three injections of 0.5 cc. of solution of posterior pituitary every two hours. When this treatment failed to complete the abortion the uterus was evacuated. In 72.9 per cent of the cases of inevitable abortion, completion occurred spontaneously or with

the assistance of drugs. Of 481 cases of incomplete abortion, infection was present on admission in 52 per cent. Expectant treatment was followed until the fever subsided, unless hemorrhage necessitated more active measures. Five days was found to be a satisfactory period to allow between the subsidence of fever and evacuation of the uterus. When the temperature, however, failed to return to normal in a week, the retained products were removed from the uterus with as little trauma as possible. If it was necessary to dilate, great care was taken not to split the cervix, to avoid any pathway for the entry of micro-organisms into the parametrium. If the uterus could not then be evacuated digitally, a blunt curet was used only to explore the uterus. When drawn gently over the uterine surface, if an obstruction was located, a slightly firmer pressure was made to remove it, but curettage was not performed. The uterus was flushed with a mild antiseptic solution, when retained products ceased to come away with the flushings, the curet was abandoned.

Four hundred and sixty-one cases required operative intervention to evacuate the uterus completely, and 72 per cent of these later showed some rise in temperature, while in only 17 per cent of the spontaneously completed abortions was there any exacerbation of infection. Active infection was present in more than half of the cases of complete abortion on admission to the hospital, if the temperature did not fall with bed rest in such cases, treatment by means of intra uterine injections of glycerin was undertaken. All but one of the eighteen patients who died was infected at the time of admission, in the one fatal case, septicemia became apparent six days after curettage for subinvolution.

The mortality rate for the entire series of 1,000 abortions was 1.8 per cent. Mortality from abortion is due chiefly to sepsis following illegal interference with pregnancy, it is therefore preventable.

SOME FAILURES OF SURGICAL TREATMENT IN GASTRODUODENAL ULCERS

The operation of partial gastric resection has won for itself a place of major importance in the treatment of gastroduodenal ulcers. In the removal of the ulcer-bearing area, enthusiasts on behalf of resection thought they had found a happy solution of the therapeutic problem of peptic ulcer. Careful statistical studies of a later period were able to bear out this contention only in part. The occurrence in a not too negligible percentage of cases of grave postoperative complications, recurrences and failure to cure the patient of his disease or to relieve him of his symptoms suggests that interference with normal physiologic relationships of the motor and secretory functions of the stomach and duodenum are not always in themselves innocuous.

Operative measures for the cure of gastroduodenal ulcer aim at the reduction of the gastric secretion and the removal of motor or mechanical hindrance to the

¹ Parish, T. N. A Therapeutic Study of Abortion. J. O. & Graces. Feb. 1935. 42: 116 (Dec.) 1935.

emptying of the stomach contents Gastro-enterostomy introduces a new factor into the evacuating mechanism of the stomach, that of hydrostatic pressure The normal peristaltic evacuating force becomes predominant in a gastro-enterostomized stomach toward the completion of the emptying process The greater portion of the stomach contents is still conducted along the pyloroduodenal route except where cicatricial stenosis or a special operative procedure prevents its passage The motility of the stomach after a gastro-enterostomy is completely dominated by the factor of hydrostatic pressure The emptying will depend principally on the size of the anastomotic stoma There frequently results a "dumping" stomach The development of a sort of a new pyloric ring and bulb with active retention of stomach contents takes place not uncommonly after the first operation of Billroth With the introduction of roentgenologic study of the relief of the gastric mucosa and its direct inspection by the gastroscope, it was established that most operative procedures on the stomach, and in particular gastro-enterostomy, are followed by a diffuse inflammation of the mucosa The gastric rugae in roentgenologic studies of the mucosal relief appear enlarged, particularly near the stoma, giving rise at times to a difficulty in differentiating this condition from carcinoma The gastroscope reveals swelling and redness of the mucosa The inflammation may develop into atrophic gastritis, with consequent lowering of the acid secretion and cure of the ulcer It may, however, persist as an acid gastritis with high acid secretion, in which case it is likely to lead to a recurrence of the original ulcer or to formation of a peptic marginal jejunal ulcer The finely balanced relationship between the gastric motility and the gastric secretion is no longer operative after a surgical intervention While the stomach rapidly empties itself, the secretion of the gastric juice continues and now acts on the empty stomach The condition is analogous to the experiment in which high gastric acidity in starved animals is maintained by histamine injections or by sham feedings with the aid of an esophageal fistula The combination leads in both human beings and experimental animals to ulcer formation

Even partial gastric resection fails to lower the gastric secretion to the degree heretofore believed The glands of the pyloric region secrete an alkaline juice, while those of the corpus portion secrete hydrochloric acid and the ferments The regulation of the acidity, however, is localized in the pyloric zone Here humoral influences arise which are conveyed by the blood stream to the glands of the corpus Thus it is believed that the generally favorable results of the first and second operations of Billroth and their modifications are to be accounted for not so much by the removal of the ulcer-bearing area as by the loss of the acid-stimulating area The effect is further promoted by the diminution in size of that portion of the stomach which secretes hydrochloric acid and the ferments The simple experiment

of histamine injection demonstrates that the stomach after a partial resection is still capable of secreting acid juice

Disturbances in motility and secretion attendant on operative intervention may lead to complications consisting of vomiting and acute dilatation of the stomach Unless rapidly relieved, hypochloremic coma and death will supervene Late complications may arise as the result of motor disturbances, such as the already mentioned "dumping" stomach, stenosis of the new stoma, compression of the efferent loop of jejunum by the distended afferent loop and adhesions causing strangulation Probably the most frequent complication is inflammation of the mucosa of the stomach, the duodenum and the first coil of jejunum It has been most frequently observed following gastro-enterostomy, less often after the second Billroth operation and least often after the first Among the more serious and disappointing late complications, recurrence of the ulcer and formation of a marginal jejunal ulcer must be mentioned Because of its greater tendency to bleed, to perforate into the free peritoneal cavity, to grow callous and to resist treatment, jejunal ulcer has come to be considered a more formidable condition than the original disease Penetration of a jejunal ulcer into the transverse colon with the formation of gastro-jejunocolic fistula is manifested by true fecal vomiting and diarrheal stools with undigested contents The prognosis is utterly bad unless relieved by the difficult operation of partial resection of the stomach, the involved segment of the jejunum and of the transverse colon and the reconstruction of the continuity of the gastro-intestinal tract Digestive disturbances develop from such causes as artificially produced achylia, loss of the influence of the duodenal secretions, and the too rapid passage of the gastric contents into the intestinal canal Loss of the duodenal reflex may lead to gall-bladder stasis and cholelithiasis The effect of the removal of a considerable portion of the stomach on the organism as a whole manifests itself at times by the development of secondary anemias of hypochromic type and rarely by hyperchromic anemia of the pernicious type

Constitution undoubtedly plays an important part in the tendency to recurrence of ulcer According to von Bergmann, persons with "vegetative stigmas" are particularly vulnerable The milder types of digestive complications can be successfully treated by rest, diet and internal therapy The more stubborn cases, particularly those following a gastro-enterostomy, are best treated by a partial resection One, however, must not forget that there are cases, fortunately few, in which a second and even a third resection is followed by the recurrence of symptoms and new ulcer formation

In explanation of these "surgically incurable" cases, Kalk¹ advances the theory of an anatomic peculiarity,

¹ Kalk, Heinz Das Erfolgrlos operierte Geschwur des Magens und Zwolfingerdarmes *Chirurg* 8 May 15 1936

namely, an unusually long zone of pyloric glands, such as exists in moles and guinea-pigs. But most observers blame the constitution and the ulcer "diathesis."

Consideration of postoperative complications is in no sense a condemnation of the surgical treatment, which has come to be recognized by the internist as well as by the surgeon as a valuable and in many cases the more successful method of treating gastroduodenal ulcer. It should, however, make the indication for operative intervention, as well as the choice of the operation, a matter of careful individual study in each case.

Current Comment

LEAD IN HUMAN BONES

Much has been written¹ of the ways by which lead may enter the body, its relatively transitory occupation of soft tissue areas, and its final storage in the skeleton, to which, after only a few days, a large part of the absorbed unexcreted lead gradually migrates. The lace-like trabecular structure has been credited as the special bony tissue which holds lead and may release it under the influence of certain biochemical conditions induced within the living organism through medication or by certain pathologic states. The mean daily intake of lead derived from ordinary food may reach 0.25 mg., an amount, however, no greater than that readily excreted by the body, hence, after a "substantial constant concentration of lead" in the tissues has been reached, a further accumulation is normally avoided.² Apparently it may take many years to arrive at such a steady state between intake and output. Human fetuses have been reported³ to contain small but definite amounts of this metal, and there are indications⁴ of a progressive increase in the lead content of human bones from infancy to old age without histories of specific exposure to lead. A similar chronological increase in the lead content of teeth apparently also occurs under seemingly normal conditions.⁴ Reports of many investigators indicate a wide but uneven distribution of lead in soft tissues. Likewise in bony structures Tompsett⁵ recently furnished confirmatory and extended evidence that, without specific exposure to lead, different bones contained unlike quantities. He found that the shafts of the femur and tibia housed larger amounts of this metal than either ribs or vertebrae. The probability of an extensive but unequal distribution of lead in tissues, especially skeletal and the so-called normal level varying with age, suggests the complexity of the problem of interpreting the presence in human bodies of lead occurring in even relatively large amounts. Tompsett has suggested that in cases of suspected lead poisoning, different bones should be examined. For significant

interpretation of even such extended data, however, one would need to compare such results with values obtained for the same bones belonging to the same age groups obtained from bodies of persons who had suffered no known exposure to lead during their lifetime.

DETECTION OF OCCULT BLOOD IN THE STOOL

Small hemorrhages in the gastro-intestinal tract may escape recognition by the usual tests for blood in the stool but can be detected with a high degree of exactitude by the spectroscope. The studies of Häcker,¹ Haurowitz,² Boas³ and other coprohematologists show that ingested blood is eliminated chiefly as hematin, which is an iron-containing nonprotein decomposition product of hemoglobin. The usual elimination curve, according to Häcker, reveals a rapid excretion of hematin within the first twenty-four hours. The peak of elimination of kopratin (reduced hemin) is reached in from two to three days, while that of the porphyrin bodies is delayed to the third or fourth day. Attention is directed to one of these porphyrin bodies, kopratoporphyrin or deuteroporphyrin, for its presence has been found by some of these investigators to be helpful in the diagnosis of minute hemorrhage originating from carcinomatous or other ulcerative processes in the gastro-intestinal tract when the stool specimens are negative for hematin. Routine tests for kopratoporphyrin were obtained in three out of five cases of gastric carcinoma studied by Häcker, while the test was positive in only one of his forty-one cases of gastric ulcer. The term porphyrin literally means a purplish red pigment (Greek porphyra, purple). Chemically, it is iron-free hemin. The porphyrins are basic constituents of pigments such as chlorophyll, bile pigments, muscle pigments and cytochrome as well as hemoglobin and are important not alone in the respiration of animals and plants but also in the synthesis of sugar from carbon dioxide and water. As illustrated by the synthetic studies of H. Fischer,⁴ the porphyrins are substituted products derived from porphin. Porphin, the fundamental nucleus common to hemoglobin, chlorophyll and other derivatives, consists of four linked pyrrole nuclei. Koproporphyrin occurs normally in the feces and urine, and uroporphyrin is found in the urine in porphyrinuria. All the porphyrins display four absorption bands in alkaline solution, but the spectrographic appearance is distinct for each porphyrin. The complex methods employed in the isolation of kopratoporphyrin discourage extensive use of the kopratoporphyrin test. An immunologic method for the detection of human blood in the stool would be ideal, but the facts that hematin is not endowed with antigenic properties and that globin, which may perhaps give rise to a specific antibody response, is decomposed in the intestinal tract precludes such a test for the present at least.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Nurse Anesthetist Lawful When Under Medical Supervision—The Supreme Court of California has sustained the judgment of the court below that refused to enjoin a nurse employed by a hospital from administering general anesthetics in connection with surgical operations. The surgeon, said the court, has the power, and therefore the duty, to direct the nurse and her actions during the operation. Nurses, during the preparation for and progress of an operation, are neither diagnosing nor prescribing within the meaning of the medical practice act, it is the legally established rule that they are but carrying out the orders of the physicians, to whose authority they are subject.

CONNECTICUT

Results of New Marriage Law—Since January 1 it has been compulsory for couples desiring a license to marry to have a blood test for syphilis. Up to July 6, according to the state health department, about one blood test out of every 100 made at the state department of health laboratories had been reported distinctly positive for syphilis.

Personal—Drs John T Winters and Francis L Lundborg were appointed police surgeons of West Hartford, June 1, succeeding Dr Frederick E Kunkel resigned.—Dr Francis G Blake, Sterling professor of medicine, Yale University School of Medicine, New Haven, was awarded an honorary degree of doctor of science by Dartmouth College, Hanover, N H, June 14.

Society News—Dr William Dameshek, Boston, read a paper before the Bridgeport Medical Association in Bridgeport, June 2, on "Recent Advances in Hematology."—The Connecticut Association of Public Health and Clinical Laboratories was recently addressed by Drs Alfred L Burgdorf, Hartford, who discussed the state marriage license law, and Elliott S A Robinson, Boston, "Immunologic Application of Placental Extracts."—The Connecticut Society for Mental Hygiene held its twenty-eighth annual dinner meeting in Greenwich, May 22. Speakers included Dr Charles C Burlingame, Hartford whose paper was entitled "When Clifford Beers Began and Now", Dr Clements C Fry, New Haven, "The Anatomy of Personality," and Charles-Edward A Winslow, Dr PH, New Haven, who was toastmaster. Officers include Dr Winslow, president, and Dr Burlingame, vice president.

ILLINOIS

Poliomyelitis and Typhoid—Eight new cases of poliomyelitis were reported for the week ended July 14, making the total throughout the state for this week the highest recorded up to this date in any one week since 1932, newspapers reported. It was stated that three cases were reported from Cook County, two from Winnebago, and one each from De Witt, Kane and Macon counties. Typhoid, with twelve new cases during the same week, reached a new weekly high for the year.

Health at Peoria—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended July 11, indicate that the highest mortality rate (27.5) appears for Peoria and that the rate for the group of cities as a whole is 11.9. The mortality rate for Peoria for the corresponding period last year was 11.4 and for the group of cities 10.7. The annual rate for eighty-six cities for the twenty-eight weeks of 1936 was 12.8 as against a rate of 12.1 for the corresponding period of last year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Chicago

Births Must Be Reported Within Ten Days—Physicians are asked to recognize the significance of reporting the births of infants to the board of health in compliance with an Illinois statute making it mandatory that all births be reported

within ten days after they occur. Recently it was found necessary to bring suit against some physicians who failed to report births on time. The board is reluctant to initiate such proceedings. The reporting of births is, however, a civic duty.

Chicago Leads in Traffic Fatalities—Chicago reported more automobile traffic deaths for the first five months of 1936 than any other city in the country, according to a report of the National Safety Council. Seventy-nine deaths were recorded during May as compared with forty-nine in May 1935. For the first five months of 1936, 315 fatalities were reported as against 305 for the corresponding period last year. For the country as a whole, traffic deaths in May 1936 were 7 per cent higher than for May 1935.

Memorial to Dr Wilder—A memorial to the late Dr William H Wilder has been established in the form of the William Hamlin Wilder Foundation, according to an announcement of the Chicago Ophthalmological Society. Its purpose will be to establish and maintain a lectureship in ophthalmology or an allied topic. The lecture will be given every year and the interest from a fund of \$10,000, now being raised, will be used for the payment of an honorarium to the lecturer and to defray expenses of publication of the lecture. The administrative details are vested in a committee composed of the president and the three most recent past presidents of the Chicago Ophthalmological Society, while the financial details will be managed by the Northern Trust Company. Friends and colleagues of the late Dr Wilder are invited to send their contributions to the Wilder Foundation, Northern Trust Company of Chicago. At the time of his death in 1935, Dr Wilder was professor emeritus of ophthalmology, Rush Medical College. He had served as president of the American Academy of Ophthalmology and Otolaryngology in 1931 and of the American Ophthalmological Society in 1918. At one time he was vice president of the Illinois Society for the Prevention of Blindness. He was chairman of the Section on Ophthalmology of the American Medical Association in 1907-1908 and a member of the House of Delegates during 1926, 1927, 1928, 1930 and 1931.

INDIANA

Society News—Dr Goethe Link, Indianapolis, discussed the "Diagnosis and Treatment of the Less Obvious Thyroid Diseases" before the Jefferson County Medical Society in Madison recently. Dr James O Ritchey, Indianapolis, discussed diseases of the chest before the society, June 22.—At a meeting of the Jasper-Newton County Medical Society in Rensselaer, May 28, Dr George J Garceau, Indianapolis, spoke on diseases of the joints.—The Wabash County Medical Society was addressed in Wabash, June 3, by Drs Jack E Pilcher, Frank B Ramsey and John H Greist, Indianapolis, on "Postoperative Complications and Their Treatment."—Dr Angus C McDonald, Warsaw, discussed "Physiologic Action of Digitals" before the Kosciusko County Medical Society in Mentone, May 12.—At a meeting of the Wayne-Union Counties Medical Society in Liberty, June 11, Dr Henry B Freiberg, Cincinnati, spoke on management of prostatism.

IOWA

Dr Nomland Appointed Head of Department—Dr Ruben Nomland, for the past six years instructor in dermatology and syphilology, Rush Medical College, has been appointed professor and head of the recently organized department of dermatology and syphilology at the State University of Iowa College of Medicine, Iowa City effective July 1. Dr Nomland graduated at Rush Medical College in 1925. He spent three years at the Mayo Foundation, specializing in dermatology and syphilology. He has been a member of the faculty at Rush for eight years.

KANSAS

Personal—Dr Mirl C Ruble Parsons has been named a member of the state board of medical examination and registration for a term of four years, he succeeds Dr John D Pace, Parsons.—Dr Mary A T DeMotte, Phillipsburg, has been named health officer of Phillips County, and Dr Grant R Hastings, Lakin, of Kearny County.

Liaison Committees—A plan is under way to organize liaison committees in the Kansas Medical Society to work with the state board of health and provide a statewide and unified method by which the society may offer closer cooperation and assistance in administration of the Social Security Act and other health programs of the state. These committees are

composed of one chairman and two members representing each county medical society and the members in counties which do not maintain chartered societies they will serve in a liaison capacity with the physicians of their county, the county health department the state board of health and other public health agencies. Dr Howard L. Snyder, Winfield, president of the state medical society requested that these committees be formed by July 15, the state journal reports.

KENTUCKY

Illegal Practitioner Sentenced.—Clyde Barlow was recently convicted of practicing medicine without a license and fined \$50 by Judge Strange in the Powell County Court, Stanton. Failing to pay, he was sentenced to work out the fine and costs at hard labor.

Dr Moore Receives Award.—Dr John Walker Moore, dean of the University of Louisville School of Medicine, received the university's 1936 Award of Merit. Among points mentioned in his citation were the following "significant contribution through research on cardiovascular functions, establishment a decade ago of the student unit system of clinical instruction, effective and stimulating teaching." Dr Moore has been associated with the university since 1915. He was made professor of medicine in 1923 and dean in 1928. He was graduated from the University of Pennsylvania School of Medicine in 1912.

School for Health Officers.—The annual school for city and county health officers was conducted by the state department of health in Louisville, June 3-6. Dr Thomas Parran Jr, surgeon general, U. S. Public Health Service, Washington, D. C. spoke at a dinner meeting and other guest lecturers were Dr Clifford E. Waller of the U. S. Public Health Service, on training of public health personnel. Dr Joseph E. Moore, Baltimore, syphilis. Dr Paul P. McCam, Sanatorium, N. C., tuberculosis control, and James O. Clarke, B. S., of the U. S. Food and Drug Administration, dangers from spray residues on fruits and vegetables.

MASSACHUSETTS

Changes at Harvard.—The following promotions on the faculty of Harvard University Medical School Boston, recently appeared in the *New England Journal of Medicine*:

Dr Robert M. Green, associate professor of applied anatomy.
Dr Charles F. McKhann, associate professor of pediatrics and communicable diseases.
Dr Jacob E. Finesinger, assistant professor of psychiatry.
Dr William G. Lennox, assistant professor of neurology.
Dr Henry R. Viets, associate in neurology.
Dr Harry C. Solomon, associate professor of psychiatry.

Personal.—Dr William B. Castle, associate professor of medicine, Harvard University Medical School, Boston was awarded the honorary degree of doctor of medicine by Utrecht University, June 24 the tercentenary of the university, according to the *New England Journal of Medicine*.—Dr Horace Binney has been appointed chief of staff at Boston City Hospital succeeding Dr David D. Scannell, who has been surgeon in chief and chairman of the surgical staff since July 1931. Dr Scannell resigned to devote his time to private practice, it is reported.—Dr William E. Castle, since 1903 professor of genetics Harvard University, Boston will retire in September with the title of professor emeritus. He has been associated with the university since 1903.—Dr Robert T. Monroe, associate in medicine Harvard University Medical School, has been appointed physician at the Peter Bent Brigham Hospital, effective September 1. He will succeed Dr Reginald Fitz.

Safety Conference.—The fifteenth annual Massachusetts Safety Conference was held in Boston recently, under the auspices of the Massachusetts Safety Council and cooperating organizations. One session was devoted to industrial health problems with the following speakers:

Robert D. Evan, Ph.D., assistant professor of physics Massachusetts Institute of Technology, Radium Poisoning.
Edward C. Riley, supervising engineer Massachusetts granite dust control project, Dust Control in the Small Granite Plant.
Philip Drinker, Ch.E., associate professor of industrial hygiene Harvard School of Public Health, The Nose as a Natural Dust Filter.

The discussion for this program was led by Dr Anthony J. Lanza, assistant medical director Metropolitan Life Insurance Company. Other speakers included Dr Timothy Leary, medical examiner Suffolk County on Carbon Monoxide Gas or Indigestion. Dr Cassius H. Watson, president National Safety Council and medical director American Telephone and Telegraph Company, New York, "The National Outlook for Greater Industrial Safety." Dr Harry K. Messenger of the Massachusetts Eye and Ear Infirmary, Boston, "Essentials of Eye Examination in Industry."

MICHIGAN

Personal.—Dr John F. Prendergast has resigned as medical director of Receiving Hospital, Detroit, to engage in private practice. Mr G. R. Harris, superintendent of Receiving Hospital, has been appointed to succeed Mr John F. Ballenger as general superintendent of the department of public welfare and administrator of the Wayne County Welfare Administration in Detroit. Both changes are effective July 31.—Dr George P. Myers, Detroit, has been appointed chief surgeon of the Michigan Central Railroad and acting medical director of the New York Central Lines.

Children's Clinic Dedicated.—The new Children's Clinic established by the Children's Fund of Michigan was dedicated in Traverse City, June 24, with Senator James Couzens delivering the principal address. Several considerations enter into the founding of these clinics by the Children's Fund: (1) giving the rural child the same chance for adequate medical care as the urban child, (2) to make possible observation in the hospital of certain juvenile cases requiring prolonged study, (3) to provide training centers for physicians and nurses, and (4) to develop methods and facilities which can be used by other child health agencies. The fund locates each clinic adjacent to a well operated general hospital to keep from building additional hospital beds. In Traverse City Munson Hospital has been selected.

Society News.—The Eaton County Medical Society is now publishing a bulletin. Dr John T. Hodgen, Grand Rapids, discussed osteomyelitis at a recent meeting of the society.—At a meeting of the Ionia-Montcalm Counties Medical Society in Ionia, June 9, Dr Francis A. Hargrave, Ionia, was the guest of honor in recognition of his completion of fifty years in the practice of medicine. Speakers included Dr Richard R. Smith, Grand Rapids, on cancer.—Dr Carl V. Weller, Ann Arbor, discussed "The Pathology of Automobile Accidents" at a meeting of the Washtenaw County Medical Society recently. Lieut. Herbert McCaske of the Detroit Police Department spoke on "Our Traffic Problem", Dr Max M. Peet, Ann Arbor, "First Aid Treatment of Injuries to the Head and Back," and Dr Charles L. Washburne, Ann Arbor, "Management of Injuries to the Body and Extremities."

MINNESOTA

Osteopath Receives Suspended Sentence.—Wayne A. Hockett, who holds a license to practice osteopathy in Minnesota, pleaded guilty in Owatonna, April 20, to practicing medicine without a license. This was said to be the first arrest in eight years of an osteopath on this charge. Hockett, who had practiced nearly two years in Waseca, had between March 2 and March 21 written two prescriptions for medicine to be taken internally by one Max Schoenfeldt, who was suffering from cancer of the pancreas with metastasis to the liver. Hockett also gave Mr Schoenfeldt two injections in the arm of a so-called cancer serum, for which he received \$150 in advance. A third injection was to be given but, because of the severe illness of the patient, was never administered. Mr Schoenfeldt died March 26. Following a complaint by a relative, \$100 of the fee was returned. A release, which Hockett had drawn up by his attorney, specifically stated that Hockett had treated Schoenfeldt for cancer. It also provided that the widow was to return to Hockett the remainder of the capsules and pills then in her possession. When Hockett was interviewed he stated he did not know the name or the ingredients of the serum that he had injected in Mr Schoenfeldt's arm. Judge Senn sentenced Hockett to pay a fine of \$250 or serve 120 days in the Waseca County Jail but suspended the sentence pending Hockett's good behavior and on condition that he refrain from violating the medical practice act in the future.

MISSISSIPPI

Course on Pediatrics.—A course in pediatrics opened in Clarksdale, July 6 with Dr Robert A. Strong, professor of pediatrics Tulane University of Louisiana School of Medicine, New Orleans, as the lecturer. The course is sponsored by the Mississippi State Medical Association, the state board of health, the school of medicine and the graduate school of medicine at Tulane and the state hospital association in cooperation with the Mississippi State Pediatric Society. The lectures cover a discussion of the new-born nutritional requirements, nutritional diseases in infancy and childhood immunizations, and the most frequent causes of vomiting in infancy. The course consists of five lectures a week and will continue ten consecutive weeks throughout the state.

MISSOURI

Society News—The Lawrence, Stone and Barry County Medical Society was organized in Aurora, June 24, with Dr Leonard Mason Lyons, Pierce City, president. The new society takes the place of the Barry County Medical Society. Other officers are Drs Lewis H. Ferguson, Monett, vice president, and Jesse A. Stocker, Mount Vernon, secretary. Its next meeting will be in September.—Dr Thomas G. Orr, Kansas City, discussed "Treatment of Diseases of the Gall Tract" before the Buchanan County Medical Society, June 3.—At a meeting of the Dallas-Hickory-Polk County Medical Society in Halfway, June 2, Dr Ernest Loyd Cartwright, Springfield, spoke on "Abnormal Conditions in Pregnancy."—The Cole County Medical Society was addressed May 21, by Drs Mazyck P. Ravenel, Columbia, and George D. Kettlekamp, Koch, on prevention and early diagnosis of tuberculosis. The meeting was a joint one with the Cole County Tuberculosis Society and the Parent-Teacher Association.

NEW MEXICO

Society News—Dr James R. Scott, Albuquerque, was elected president of the New Mexico Public Health Association at the annual meeting in May. Paul S. Fox, C.E., Santa Fe, is secretary. The association adopted a resolution petitioning the President and Congress of the United States to assume the function, through proper administrative channels, of preventing the advertisement of remedies sold for profit for the alleged cure of cancer, tuberculosis and syphilis.

NEW YORK

Lake Keuka Meeting—The thirty-seventh annual meeting of the Lake Keuka Medical and Surgical Association was held at Penn Yan July 16-17. Speakers included Dr Floyd S. Winslow, Rochester, on 'Trends in the Progress of Medicine', Dr Charles C. Higgins, Cleveland, "Recent Experimental Observations Dealing with the Production and Solution of Urinary Calculi and the Clinical Management of Patients", Dr Stuart W. Harrington, Rochester, Minn., 'Surgical Treatment of Diaphragmatic Hernia' and B. E. Sackett, LL.B., of the federal bureau of investigation, Buffalo, 'Work and Functions of the Federal Bureau of Investigation'.

Pharmacists Condemn Socialized Medicine—At the annual meeting of the New York State Pharmaceutical Association at Bolton's Landing, June 17, Mr David N. Ditchek, Brooklyn, chairman of the committee on socialized medicine and compulsory health insurance, presented a report in which he pointed out that changes in systems of medical, dental and pharmaceutical practices will affect the pharmacist no less than other professions. He urged pharmacists to become interested in the movements toward socialized medicine. The association adopted a resolution condemning the New York Edison Company, a corporation, for entering the practice of medicine, dentistry and pharmacy.

New York City

Jacobi Fellowship Awarded—The Mary Putnam Jacobi fellowship of \$1,000 for graduate work abroad has been awarded to Dr Angeline F. Simecek. Dr Simecek graduated from the University of Nebraska College of Medicine, Omaha, in 1933 and for the past three years has been on the staff of the New York Infirmary for Women and Children. The fellowship is offered by the Women's Medical Association of New York City.

Society News—The Physicians Equity Association of America, Inc., held its first annual golf tournament and dinner at the Scarsdale Golf Club, Hartsdale, June 30.—The Brooklyn Thoracic Society was recently formed with Dr Foster Murray as president, and Dr Alexander L. Louria as secretary. The society plans to hold its meetings in the building of the Medical Society of the County of Kings and to hold stated clinics in the hospitals of Brooklyn. The first scientific meeting will be the third Friday in October.

Gifts to New York University—Among recent gifts to New York University are the following for medical purposes.

Carnegie Corporation of New York \$8,750 for support of the college of medicine.

Milbank Memorial Fund \$1,200 for the gonococcus project under the direction of Dr Charles Hendee Smith.

Lucius M. Littner \$1,000 for a special fund for the department of forensic medicine.

International Cancer Research Foundation \$1,000 for research in cancer under direction of Prof Robert Chambers, Washington Square College.

Sundry donors \$1,445 for research in pneumonia under direction of Dr Jesse G. M. Bullowa.

New York Reduces Automobile Death Rate—The National Safety Council reports that for the first five months of this year the city death rate from automobiles was 93 per hundred thousand, the lowest achieved by any large city in the country. The number of persons killed was 276, as compared with 349 in the same period last year. The city won second place last year in the safety contest sponsored by the council and is at present leader in this year's contest. New York State has made a 14 per cent reduction in automobile fatalities for the first five months of this year. 829 persons were killed as compared with 965 for the corresponding period of 1935.

Hospital Positions Under the Civil Service—Mayor La Guardia has signed a resolution adopted by the Municipal Civil Service Commission placing under civil service many positions in the city department of hospitals hitherto exempt. Approval by the state civil service commission is necessary to make the ruling effective. About 4,000 persons will be affected. Present holders of the positions will take examinations to determine whether they are qualified and those found deficient will be dismissed, the *New York Times* reports. The positions placed in the competitive classes by the resolution include those of bakers, butchers, dentists, laundrymen, orderlies, supervisors, laboratory assistants and helpers, matrons, pharmacists, tailors, telephone operators, watchmen, electricians, carpenters, tin-smiths, plumbers, clerks, assistant alienists, coffee roasters and seamstresses.

OHIO

Doctors' Symphony Orchestra Completes Tenth Year—The Doctors' Symphony Orchestra of Akron ended its first decade with its sixty-first concert June 7 at the Edwin Shaw Sanatorium. During the ten years sixty-five physicians and dentists have been members of the orchestra. Its present strength is thirty-seven. Dr Alexander S. McCormick organized the orchestra and has been its director throughout the ten years.

PENNSYLVANIA

Personal—Dr George W. Reese has resigned as superintendent and surgeon-in-chief of the Shamokin Hospital, Shamokin. Dr Robert Y. Grone, Danville, was appointed chief surgeon to succeed him.—Dr Charles I. Shaffer, Ralphton, has been appointed superintendent of the Somerset County Home and Hospital, Somerset.

County Society Buys a Home—The Montgomery County Medical Society recently bought the Ersine Tennis Club, Norristown, as a permanent home and took possession July 1. A fund was started toward a home for the society in 1905, when Dr Oscar H. Allis, Philadelphia, gave ten dollars as a nucleus. Dr Allis died in 1921. Dr Walter J. Stein, Ardmore, is president of the society and Dr Edgar S. Buyers, Norristown, secretary. Dr Buyers is chairman of the board of trustees of the Medical Society of the State of Pennsylvania.

Society News—Among speakers at a meeting of the Sixth Council District of the Medical Society of the State of Pennsylvania in Philipsburg, June 4, were Drs John O. Bower, Philadelphia, on appendicitis mortality, Richard A. Kern, Philadelphia, clinical allergy, Chauncey L. Palmer, Pittsburgh, social security and Pennsylvania legislation, Alexander H. Colwell, Pittsburgh, president of the state society, the dual purpose of the medical society, scientific and economic. Walter F. Donaldson, Pittsburgh, secretary of the state society, responsibilities of membership, and John M. Quigley, Clearfield, history of medicine in Clearfield County. Drs William H. Morrow, Bellwood, and John I. Brockbank, DuBois, received certificates for fifty years of medical practice.

Philadelphia

Woman's Medical College News—Dr Martha Tracy, dean of the Woman's Medical College of Pennsylvania, after a year's leave of absence resumed her duties July 1. Dr Rose Hirschler has been appointed professor of dermatology, Dr M. Agnes Gowdey, assistant instructor in clinical obstetrics, and Dr Helen B. Thompson, assistant in clinical surgery.

Advisory Staff for Mental Hospital—Mayor Wilson has appointed an advisory staff to supervise treatment of patients at the Philadelphia Hospital for Mental Diseases at Byberry. They are Drs Wilbur P. Rickert, superintendent of the hospital, Frederick H. Allen, Charles W. Burr, Earl D. Bond, George Wilson, Frederic H. Leavitt and Wilmer H. Krusen.

Hospital News—Dr William H. Teller has been made emeritus surgeon of the Jewish Hospital and Dr Norman S. Rothschild has been elected to the staff in his place. Dr Frank

L. Tollweiler, Jenkintown has been elected head of the physical therapy department to fill the post vacated by Dr. Frank H. Krusen, who went to the Mayo Clinic, Rochester, Minn., several months ago. Dr. William Duane, Jr. has succeeded Dr. Nicholas Gotten as neurosurgeon at the hospital.

Dr. Reimann Appointed Professor at Jefferson—Dr. Hobart A. Reimann, associate professor of medicine at the University of Minnesota Medical School, Minneapolis, and Graduate School of Medicine, Minneapolis-Rochester, has been appointed Magee professor of practice of medicine and clinical medicine at Jefferson Medical College, Philadelphia, effective September 1. Dr. Reimann was associated with the Rockefeller Institute for Medical Research, New York, and Peiping Union Medical College, Peiping, China, before he went to Minnesota. The college also announced the following promotions: Drs. Martin E. Rehfuess to be professor of clinical medicine, Henry K. Mohler, clinical professor of therapeutics, and Baldwin L. Keves, clinical professor of psychiatry.

RHODE ISLAND

Society News—Dr. William A. Horan, Providence, addressed the Providence Medical Association in Providence May 4, on backache—A symposium on surgery of the biliary tract was presented at the quarterly meeting of the Washington County Medical Society, Westerly, R. I., July 8, by Drs. Frederic V. Hussey, Eliot A. Shaw, Meyer Saklad and Jesse P. Eddy III, all of Providence.

TENNESSEE

Promotions at Vanderbilt—The following physicians on the staff of Vanderbilt University School of Medicine, Nashville have been promoted to the positions indicated:

Dr. George Summers Johnson, professor of surgery
Dr. Thomas D. McKinney, professor of clinical surgery
Dr. Alvin E. Keller, professor of preventive medicine and public health
Dr. Christopher C. McClure, professor of radiology
Dr. Thomas C. Butler, assistant professor of pharmacology
Dr. Nathaniel Schorn Shofner, assistant professor of clinical surgery

Society News—Drs. Michael L. Mason, Chicago and Robert C. Derivaux, Nashville addressed the Sullivan-Johnson Counties Medical Society, Bristol, June 3, on "Infections of the Hand" and "Recent Advances in the Management of Diabetes Mellitus" respectively—Dr. Forrest S. LeTeller, Knoxville addressed the Knox County Medical Society, June 2, on "Conjunctivitis in the New-Born"—A program on maternal welfare was presented at a meeting of the Hardin, Lawrence, Lewis, Perry and Wayne Counties Medical Society May 26 at Waynesboro, by Drs. J. W. Erwin, Savannah, William T. Pride and R. A. Wallace Memphis. Samuel C. Cowan and Milton Smith, Lewis, Nashville—Dr. Benjamin C. Arnold, Jackson, addressed the Madison County Medical Society, Jackson June 2, on "Urethral Stones and Pyelitis."

WISCONSIN

Personal—Dr. Carl N. Neupert, Janesville has been appointed supervisor of public health service, a new position created under the social security plan for Wisconsin. His special work will be to establish contact with county medical societies to further tuberculin testing, reduction of gonorrhea incidence and programs of diphtheria prevention and smallpox vaccination.

Appointments to State Medical Board—Gov. Philip La Follette recently announced the following appointments to the state board of medical examiners: Dr. Henry O. McMahon, Milwaukee to succeed the late Dr. John E. Guy, Dr. Adam I. Gates, Tigerton to succeed Dr. John R. Venning, Fort Atkinson and Dr. Cornelius H. Cremer, Cashton to succeed Dr. Robert E. Flynn, La Crosse. Dr. Henry J. Gramling, Milwaukee was reappointed.

State Radiologic Meeting—The twelfth annual meeting of the section on radiology of the State Medical Society of Wisconsin was held in Kenosha June 5-6. A symposium on tuberculosis was presented by Dr. Carroll E. Cook, Chicago. Harold M. Coor, Stevens Point, Marcus Fernan Nunez and Forrester Raine, Milwaukee. Among other speakers were Dr. Henry Schmitz, Chicago, "Prevention and Treatment of Skin Reactions," Robert S. Landauer, Ph.D., Chicago, "Physical Problems in X-Ray Therapy" and Dr. Chester H. Warfield, Chicago, "Bone Tumors." Dr. Hans W. Hefke, Milwaukee was elected president and Dr. Russell F. Wilson, Beloit secretary.

Physicians for Fifty Years—Drs. Albert J. Hodgson and Joseph B. Noble, Waukesha, were guests of the Waukesha County Medical Society at a dinner at The Spa Waukesha, June 3, in honor of the fiftieth anniversary of their medical practice, the *Wisconsin Medical Journal* reports. Drs. Richard E. Davies and Frederick J. Woodhead, Waukesha, paid tribute to the guests of honor and Dr. Arthur W. Rogers, Oconomowoc, councilor of the first district, also made a short address. Dr. Hodgson and Dr. Noble were born in 1858 and both were graduated from Rush Medical College, Chicago, in 1886. Dr. Hodgson founded The Spa twenty-six years ago, he has been retired from active practice for many years. Dr. Noble has been physician to the state industrial school for fifteen years. Dr. Frank L. Grover, Hartland, president of the county society, had charge of arrangements.

Conference on Industrial Medicine—An industrial medical conference will be held at Wausau, July 27-28, under the auspices of Employers Mutuals insurance firms of Wausau in commemoration of their twenty-fifth anniversary. Dr. Morris Fishbein, Chicago, editor of THE JOURNAL, will be the speaker at the banquet Monday evening, July 27, at the Rothschild Pavilion, near Wausau, on "Medical Organization and the Nature of Medical Practice." At the medical sessions at the Grand Theater, speakers will include:

Mr. Voyta Wrabetz, chairman of the industrial commission of Wisconsin, "The Relationship of the Medical Profession to the Compensation Law"
Dr. John Albert Key, St. Louis, "Internal Derangements of the Knee"
Dr. Edwin W. Ryerson, Chicago, "Injuries and Disabilities of the Shoulder Joint"
Dr. Alfred W. Adson, Rochester, Minn., "Surgical Treatment of Peripheral Nerve Injuries"
Dr. Erwin R. Schmidt, Madison, "Modern Treatment of Brain Injuries."
Dr. John W. Powers, Milwaukee, "Treatment of Compound Fractures and Contaminated Wounds."

PUERTO RICO

University News—Five students from the University of Cincinnati are doing special work at the School of Tropical Medicine, University of Puerto Rico, San Juan. Dr. Thomas J. LeBlanc, professor of preventive medicine, University of Cincinnati School of Medicine is in charge of the work of these students. They are Dr. Armin T. Wilson and Messrs. Calvin F. Warner, William M. Fischbach, Homer H. Kohler and Kenneth Hausfeld.

GENERAL

Bequests and Donations—The following bequests and donations have recently been announced:

St. Luke's Hospital, New York will eventually receive \$3,000,000 from the estate of the late Mrs. Helen Slade Ogilvie after the death of her daughter. Neurological Institute of New York will also receive \$10,000.
Northern Westchester Hospital, Mount Kisco, \$4,000 by the will of the late Charles A. Halstead.
Tarrytown Hospital Association, \$1,000 from the estate of Edith C. Batt.
New York Eye and Ear Infirmary, Presbyterian Hospital and Roosevelt Hospital, \$10,000 each from the will of the late Samuel Hopkins.
Pennsylvania Hospital, Philadelphia, \$12,000 by the will of the late Miss Rebecca A. Hough.
Methodist Episcopal Hospital, Philadelphia, \$25,000 by the will of Ida Simpson.
Presbyterian Hospital, Chicago, \$25,000.
Hospital Association of Lake Forest, Ill., \$10,000 by the will of the late C. H. McCormick.
Montefiore Hospital, New York, \$5,000 by the will of the late Mrs. Bella Kaufman.
Tacoma General Hospital, Tacoma, Wash., will benefit from the will of the late H. A. Rust, who provided that the income from half his estate of \$60,000 be given to the hospital after the death of his youngest grandchild to maintain a free ward for indigent children.

Changes in Status of Licensure—The state board of medical education and licensure of Pennsylvania has reported the following action taken at a meeting June 26:

Dr. Charles W. Dubin, Alexandroff, Philadelphia, license revoked because of his conviction of violation of the Harrison Narcotic Act.
Dr. Thomas Henry McWhorter, Philadelphia, license revoked because of violation of the narcotic law and association with unethical practitioners.
Dr. James Edwin Frey, now of Joplin, Mo., license revoked because of his conviction in Montana of violation of the narcotic law.

The board of medical examiners of Oklahoma reports the following action taken at a meeting June 11:

Dr. Horace Porter Routh, Tulsa, license suspended for five years for violation of narcotic laws.
Dr. Alonzo B. C. Davis, Oklahoma City, license revoked for unprofessional conduct having performed criminal abortions.
Dr. Guy E. Brewer Garber, license revoked for unprofessional conduct having performed criminal abortions.
Dr. Franklyn Albert Howell, Oklahoma City, license revoked for violation of narcotic laws.
Dr. Young Anderson Howell, Mountain View, license suspended for one year for violation of narcotic laws.

The State Medical Board of the Arkansas Medical Society reports the following action taken at a recent meeting

Dr Charles Othello Ozias Eureka Springs license revoked for advertising a special ability to treat or cure chronic and incurable diseases.

Dr Hektoen Named Chairman of National Research Council—Dr Ludvig Hektoen, Chicago, has been appointed chairman of the National Research Council to succeed Frank R Lillie, Ph.D., Chicago. For three terms of one year each, Dr Hektoen has been chairman of the division of medical sciences of the council, which has headquarters in Washington, D C, and acts in an advisory capacity to the federal government in research matters. In 1887 Dr Hektoen graduated from the College of Physicians and Surgeons of Chicago. He has served as pathologist to Cook County Hospital, lecturer in pathology at Rush, physician to the coroner's office, professor of pathology at his alma mater, and professor of morbid anatomy and since 1898 as professor of pathology at Rush. From 1901 to 1934 he was professor and head of the department of pathology, Division of Biological Sciences, University of Chicago, retiring in the latter year to become professor emeritus. Since 1902 he has been director of the McCormick Institute for Medical Research. He has been editor of the *Journal of Infectious Diseases* since 1904 and of the *Archives of Pathology* since 1926. Societies of which he has been president include the Chicago Medical Society, 1919-1921, Chicago Pathological Society, 1898-1902, Association of American Pathologists and Bacteriologists, 1901, Society of American Bacteriologists, 1929, Society of Immunologists, 1927, Institute of Medicine of Chicago, 1929. In 1909 he was vice president of the American Association for the Advancement of Science and for several years has been chairman of the Committee on Scientific Research of the American Medical Association. He has received various honorary degrees and has written numerous articles on pathology, bacteriology and immunology.

Society News—The sixteenth annual meeting of the American Society for the Hard of Hearing was held in Boston May 26-30, with 575 registrants, the largest number on record. It was voted to hold biennial conferences hereafter, with zone conferences in alternate years. There are now 156 local societies in the United States.—Dr Marion C Pruntt, Atlanta, Ga, was elected president of the American Proctologic Society at the annual meeting in Kansas City in May. Dr Clement J DeBere, Chicago, was elected vice president and Dr Curtice Rosser, Dallas, was reelected secretary. The next meeting will be held in Atlantic City in June 1937.—The first National Conference on Educational Broadcasting will be held in Washington, D C, December 10-12. C S Marsh of the American Council on Education, 744 Jackson Place, Washington is executive secretary of the planning committee. All organizations interested in radio as a social force nationally or regionally, are invited to participate.—The American Congress of Physical Therapy will hold its fifteenth annual clinical and scientific session at the Waldorf Astoria, New York, September 7-11.—Dr Earle G Brown, secretary of the Kansas Board of Health, Topeka was elected president of the State and Provincial Health Authorities of North America at its fifty-first annual meeting in Vancouver, B C, June 23.—The Biological Photographic Association invites all photographers and scientists interested to attend the sixth annual convention in Boston, September 24-26, at the Hotel Lenox. Active membership is open to those whose duties include biologic photography, any one interested may become an associate member. The president is Louis Schmidt Rockefeller Institute for Medical Research, New York, and the secretary, Miss Anne Shuras, University of Pittsburgh School of Medicine.

CANADA

Personal—Sir Frederick Banting, professor of medical research, University of Toronto Faculty of Medicine, Toronto, has been elected to fellowship in the Royal College of Physicians London.—Dr Maude E Abbott, assistant professor of medicine and curator of the museum of the history of medicine at McGill University Faculty of Medicine is retiring this year, according to the *Canadian Medical Association Journal*.

University Graduate Courses—The Medical Faculty of Queen's University, Kingston, announces a graduate course in medicine, surgery, gynecology, bacteriology, radiology and special apparatus, September 7-11.—The University of Toronto Faculty of Medicine will offer a course in general surgery of the abdomen to physicians who have had satisfactory training in surgery. The course will begin September 28 and continue for a week at the Toronto General Hospital.

St Michael's Hospital, Hospital for Sick Children and the Toronto Western Hospital and at Banting Institute.—The University of Western Ontario, London, announces its annual refresher course for September 14-18.

Government Services

Changes in Public Health Service

Dr Erval R Coffey has been promoted and commissioned as surgeon and Drs Frederick T Foard and Winfield Kennedy Sharp Jr have been appointed and commissioned as surgeons in the regular corps of the public health service. Other changes include the following transfers:

Medical Intern Marion T Yates relieved at Chicago and assigned to U S Hospital for Defective Delinquents Springfield Mo for duty.

Medical Intern Emanuel Rollins relieved at U S Marine Hospital San Francisco and assigned to U S Hospital for Defective Delinquents.

Medical Intern Howard T White relieved at U S Marine Hospital St. Louis and assigned to U S Marine Hospital Stapleton N Y.

Medical Intern Earl F Gates relieved at U S Marine Hospital San Francisco and assigned to Detroit.

Appointment of Medical Officers in Regular Army

The following named first lieutenants, medical corps reserve, have been tendered appointment as first lieutenants, medical corps, regular army, with rank from July 1, 1936: Waldron Lewis Morse, Canton, Maine, Charles Bateman Perkins, Seattle, Clarence Asa Tinsman, Roxbury, Va, Gustave Freeman, Chicago, Fred James Black, Detroit, Samuel Henry Worthen Jr, Afton, Wyo, Robert Hough Jordan, Farmingdale, N Y, Clark Bolton Meador, Grand Canyon, Ariz, John Chisholm Fitzpatrick, Jamestown, N D, Levi Martin Browning, Wauwatosa, Wis. John William Kemble, Rochester, Minn, Raymond McKinley Williams, Tahlequah, Okla, Benjamin Anderson Strickland Jr, Baltimore, John William Raulston, Sheffield, Ala. Charles Henry Moseley, El Paso, Texas, William Ferrall Cook, El Paso, Erving Francis Geever, El Paso, Conn Lewis Milburn Jr, El Paso, James Thomas McGibony, San Antonio, Robert Henry Blount, San Antonio, John Kemp Davis, San Francisco, Louis Frederick Hubener, San Antonio, Wilbur Carmen Berry, San Antonio, Karl Herbert Houghton, San Francisco, Albert Charles Krukowski, San Antonio, Kenneth Somers, San Francisco, and Edward Sigerfoos, Denver.

Summary of Legislation Affecting Army Medical Department

The Seventy-Fourth Congress enacted legislation of far reaching benefit and importance to the Medical Department of the U S Army. Medical Reserve Officers Training Corps units, which have been discontinued for several years because of prohibitive legislation are being reestablished as a result of provisions of the War Department Appropriation Act. Instruction will begin in October in many of these units. Fifty officers will be added to the Medical Corps, the first increase since 1920. An increase in the enlisted force from 118,000 to 165,000 has brought about a serious shortage in medical and dental officers. Funds for maintenance of army hospitals have been increased and the appropriation for the purchase of medical and hospital supplies is the largest for this purpose in the history of the army in peace time. The sum of \$20,660 was appropriated for purchase of books for the surgeon general's library and \$37,000 was set aside for publication of the *Index Catalogue*, which has been suspended for two years. Adequate appropriations have also been provided for administration of the Army Medical Museum and for research by the medical department. Opportunity for practical training for medical department reserve officers will be improved by the increase in the appropriation for training of the officers' reserve corps. It is anticipated that the medical officers training camp at Carlisle, Pa, will be larger than in many years.

CORRECTION

Intravenous Therapy—In Queries and Minor Notes in THE JOURNAL, July 4 page 60, it was stated that Dutton's book on 'Intravenous Therapy' published by the F A Davis Company, Philadelphia in 1925 is the most extensive book on the subject available at present. Mention should have been made of a later volume on 'Parenteral Therapy' by Dutton and Lake, published by C C. Thomas Springfield Ill, in 1936.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 6, 1936

Reform of the Medical Curriculum

The General Medical Council is the body which regulates medical education. The council appointed a curriculum committee, which a year ago presented a report, which was circulated to the licensing bodies and the medical schools for their observations. In addition, observations were furnished by the minister of health, a special committee on medical education appointed by the British Medical Association, the council of the Section of Radiology of the Royal Society of Medicine, and the general council of the Trades Union Congress. Following the receipt of the observations made by the licensing bodies and medical schools a second interim report was made by the curriculum committee and was also submitted. Observations were received from twenty-two of the twenty-three licensing bodies and seventeen of the twenty-five medical schools. These were carefully considered by the committee with the result that new resolutions in regard to the medical curriculum have now been adopted by the council. These will come into operation Jan. 1, 1938, as regulations for medical education.

PREREGISTRATION REQUIREMENTS

Every applicant for registration as a medical student must pass (1) a recognized preliminary examination in general education and (2) in chemistry, physics and biology, including the fundamental facts of vegetable and animal structure, life history and function, and an introduction to the study of embryology. The examination in biology may be taken either before or after registration as a student.

THE MEDICAL CURRICULUM

The period of study must not be less than five academic years. The first two years should be devoted to professional scientific subjects, with an introduction to clinical methods. The last three years should be devoted to clinical subjects, with the clinical application of the professional scientific subjects. Throughout the whole period the student's attention should be directed to the importance of the measures by which normal health may be assessed and maintained, and to the principles and practice of the prevention of disease.

PERIOD OF PROFESSIONAL SCIENTIFIC SUBJECTS (FIRST AND SECOND YEARS)

The courses should include (1) dissection of the entire cadaver, (2) anatomy of the living body, (3) elements of human embryology, (4) histology, (5) the elements of genetics, (6) the principles of general physiology, the chemistry and physics of bodily functions to be studied as far as possible in man, (7) the elements of normal psychology, (8) methods of clinical examination including the ophthalmoscope and the examination of body fluids, (9) normal reactions of the body to injury and infections as an introduction to general pathology and bacteriology, and (10) an introduction to pharmacology.

PERIOD OF CLINICAL STUDIES (THIRD, FOURTH AND FIFTH YEARS)

A minimum period of three years should be given to clinical study at an approved hospital after passing the examination held at the close of the second year. The subjects are as follows:

1. Medicine including (a) systematic instruction in principles and practice, (b) a clinical clerkship in hospital wards for not less than one month in residence in a

hospital or conveniently nearby, during which the student is attached to the medical wards, (d) a clinical clerkship for not less than one month in a children's ward or hospital, (e) regular attendance at an outpatient department for three months, (f) regular instruction and demonstration in applied anatomy and physiology during the period of clinical studies, to be carried out by the teachers of anatomy, physiology and the clinical subjects, (g) methods of treatment, including dietetics, therapeutics and prescribing, physical therapy and principles of nursing, (h) diseases of children and child welfare, acute infectious diseases, tuberculosis, industrial diseases, psychology and mental disorder and deficiency, diseases of the skin, radiology and vaccination.

2. Surgery, including (a) systematic instruction in principles and practice, (b) assistantship to a surgeon for six months, (c) not less than one month's residence in a hospital, (d) regular attendance in a surgical outpatient department for three months, (e) instruction in surgical methods, including physical therapy, (f) instruction in minor operative surgery on the living, (g) administration of anesthetics, (h) a course of operative surgery, (i) applied anatomy and physiology, (j) surgery of infancy and childhood, ophthalmology, diseases of eye, ear, nose and throat, radiology, venereal diseases, orthopedics and dental diseases.

3. Midwifery, infant hygiene and diseases of women, including (a) systematic instruction in midwifery and gynecology, applied anatomy and physiology of pregnancy and labor, (b) clinical lectures and demonstrations, attendance on a maternity ward and inpatient and outpatient gynecologic practice for six months, (c) not less than two months as resident pupil in a maternity ward, where the student should attend not less than twenty cases, (d) instruction in antepartum and postpartum care, management of the puerperium and care of the new born infant.

4. Pathology and bacteriology, including courses in general and special pathology and morbid anatomy, clinical and chemical pathology, general and clinical bacteriology, immunology and immunization.

5. Pharmacology and materia medica, including pharmacy.

6. Hygiene and public health.

7. Forensic medicine.

8. Legal and ethical obligations of physicians.

The First Antigas School

The extensive measures which are being taken by the government for the protection of the civilian population against aerial gas attacks have been described in previous letters. The first civilian antigas school has been opened in Gloucestershire, a western county and therefore a long distance for aircraft coming from the continent to travel. The school has been established to give instruction in antigas measures to members of the public services concerned with civil air raid precautions. Later, facilities will be provided for the training of instructors of certain classes of industrial and commercial undertakings of importance. The instruction will be undertaken by the government, and it will then be for the local authorities to arrange for instruction to be given locally by men trained in the school. The equipment and cost of instruction and accommodation is provided by the government, but each student is asked to pay £1 50 a day for his food. Each course will last ten working days and be taken by thirty students, the syllabus embracing gases likely to be encountered in air attacks, technical measures of individual and collective protection, administrative and special measures of protection, and guidance in the organization and teaching of local instruction classes. Special courses are provided for the training of instructors primarily concerned in police and fire department duties and first aid and rescue work. The London police and fire departments have already had their instructors

trained, and their program involves the training of 30,000 policemen by April of next year. Special courses of a week's duration are to be provided for physicians and nurses concerned with treatment as distinguished from first aid, and others for the identification of gases. There are also courses for the training of qualified chemists in the detection and identification of gases.

Organization for Protection of Intellectual Liberty

In no country in the world is intellectual freedom greater or safer than in England, but its recent destruction over a large part of the European continent has led leading men to form an organization for the protection of freedom of thought. They include professors, scientists and writers. Prominent among them are men well known in the biologic and medical spheres. The president is Mr. Aldous Huxley, and that great name is represented also by his brother the biologist Julian Huxley. Another biologist is J. B. S. Haldane (son of the late J. S. Haldane). Most eminent of all is Sir Gowland Hopkins, late president of the Royal Society and the father of modern biochemistry. On the literary side are the Greek scholar Gilbert Murray, the military writer Capt. Liddell Hart, the international historian and authority on foreign policy C. K. Webster, and Miss Rose Macaulay. The church is represented by the dean of Canterbury and the law by Sir William Jowitt. An executive committee is organizing committees of scientists, artists, writers and others to undertake lecturing and propaganda work of all kinds. Membership is to be recruited from all the professions and the universities. Events in Germany and elsewhere have shown how easy it is to destroy intellectual freedom. In that country one of the most deplorable incidents was the complete impotence of the intellectuals against the attack. The only effective resistance was made by the Lutheran church. A rather different but analogous organization has been formed by the intellectuals in France, the Comité de vigilance, to protect the country against fascist dictatorship.

June 27, 1936

Hyperinsulinism Due to Adenoma of Islands of Langerhans

The first operation for the clinical syndrome due to hyperinsulinism was reported from the Mayo Clinic in 1926. Since then, others have been reported by American surgeons but few from Europe. Such a case was reported at the April 22 meeting of the Académie de chirurgie de Paris by a surgeon of Prague, Jirasek, and two associates. An engineer, aged 28, noticed in 1928, following rapid ingestion of food, that he staggered as if intoxicated. Similar attacks were rare during the next few years, but at intervals, it was impossible to awaken him and he would sleep for thirty-six hours. Various diagnoses had been made before he was seen by Brenner, a neurologist of Prague, early in 1933. The clinical features were those of mental confusion, rapid increase in weight, amnesia at intervals and a marked hypoglycemia. Postranecky, an associate of Jirasek, found a basal metabolism of -8 per cent and a constant hypoglycemia (42 mg. per hundred cubic centimeters) in the morning before taking food. Further study showed that a complex which is considered as being typical of hyperinsulinism existed, i. e., a constant secretion of insulin not bearing any relation to periods of digestion or fasting. The patient was thus always in danger of attacks due to hypoglycemia. Administration of hypophyseal and thyroid extracts was of no avail and operation was decided on. In view of the prolonged duration, a malignant neoplasm in the pancreas was excluded by Jirasek before operation and the diagnosis of an

adenoma of the islands of Langerhans seemed the most plausible diagnosis. The operation was performed Dec. 15, 1934 and a nodule the size of a lentil and the shape of a hazelnut was found in the tail of the pancreas. Microscopic study of the excised tumor by Siki revealed it to be an adenoma in the stroma of which were amyloid deposits. The parenchyma of the tumor corresponded in appearance to the cells of the islands of Langerhans. During the first five days after the operation there was a marked glycosuria and hyperglycemia. Following this transitory complication the reactions following the administration of dextrose alone, of insulin and of the two combined, were found to be normal. Since the operation, no attacks due to a hypoglycemia have occurred. No discomfort is experienced even after not eating for a prolonged period. The authors emphasize that one ought always to consider a hypoglycemia or even an adenoma of the islands of Langerhans when the clinical picture is that of brief periods of mental confusion, transitory aphasia or pareses or when epileptiform attacks occur in which porriomania or paroxysmal hypersomnias are noteworthy features. The importance from the medicolegal standpoint of these attacks due to a hypoglycemia cannot be underestimated. After an automobile or machinery accident, those who are responsible are unable to explain how they occurred, in view of the previous experience of the individual as a chauffeur or engineer.

Resection of Pancreas for Chronic Pancreatitis

At the April 22 meeting of the Académie de chirurgie of Paris, Mallet-Guy, a surgeon of Lyons, reported three cases in which the body of the pancreas was resected for chronic pancreatitis. The first case had been presented in May 1935. There was a history of a previous operation, by another surgeon, for a suspected perforation of a gastric ulcer, but no such condition was found. At a second operation, performed by Mallet-Guy, an edematous pancreatitis was found. In spite of drainage, the clinical signs, such as recurrent acute pain over the pancreatic region, digestive disturbances and emaciation, continued. At the third intervention, a walnut-sized area of chronic pancreatitis embedded in cicatricial tissue having been encountered in the body and tail of the pancreas, this portion was resected. An uneventful recovery with disappearance of all clinical signs followed. The resected area measured 8 by 4 cm., and microscopic examination revealed complete replacement of the glandular acini by fibrous tissue with occasional small cyst formation.

In the second case the history resembled that of a gastric ulcer over a period of eighteen years. When the patient was first seen by Mallet-Guy the symptoms were those of an acute pancreatitis. After the acute symptoms subsided, the head of the pancreas was found to be normal in appearance and consistency but the body itself was indurated. There were three large calculi in the gallbladder. The portion of the pancreas in which the area of chronic induration had been found was resected and the gallbladder drained after removal of the calculi. Microscopic examination of the specimen, which measured 85 cm. in length, revealed a sclerocystic pancreatitis. All the digestive symptoms disappeared after the operation.

In the third case the history was that of recurrent attacks of severe pain referred to the left half of the abdomen. During one of these attacks a diagnosis of acute ileus had been made. Soon after admission to the hospital, two attacks of severe pain accompanied by high temperature occurred. A hard mass could be felt in the upper part of the abdomen of the greatly emaciated woman. A diagnosis of chronic pancreatitis was made before operation, at which a greatly indurated pancreas was found that corresponded to the mass felt before operation. The body of the pancreas was also resected in this case without any difficulty. Nothing abnormal was found in the biliary tract. The resected portion of the body of the pancreas revealed, as

in the other two cases, on histologic study diffuse sclerocystic changes. The only postoperative incident was a marked transitory hyperglycemia. The resected specimen measured 8 cm in length.

Mallet-Guy stated that many cases of chronic pancreatitis are not recognized clinically, so that the condition of this viscus should be examined during every operation in the upper part of the abdomen in which no other lesion is found to explain the clinical symptoms. Resection of the body of the pancreas does not present insurmountable technical difficulty and, judging by the end results in his three cases, does not appear to be followed by any demonstrable disturbance of metabolism. In the discussion Brocq said that in the majority of cases of chronic pancreatitis the induration due to the sclerotic changes is a diffuse one and that a resection of the left half of the pancreas as was carried out by Mallet-Guy, was possible. If the induration was found to be circumscribed, a cuneiform resection could be performed.

Postoperative Hyperglycemia

The question as to the influence of operations on the urea content of the blood has been the subject of research during the past few years in French hospitals. One of the latest contributions to postoperative blood changes is that of Lambret and Driessens, presented at the April 1 meeting of the Académie de chirurgie of Paris. An increase in blood sugar is constantly observed after operations. Those which have the most influence, i. e., give rise to a hyperglycemia, are operations which have the influence of a trauma on the nervous system and on the development of polypeptides in other tissues. This hyperglycemia would appear to be due to a disturbance of the sympathetic nerves and of the adrenals. Clinical and experimental research have made it possible to combat a postoperative hyperglycemia by the simultaneous intravenous administration of a hypertonic (30 per cent) solution of dextrose, a 20 per cent solution of sodium chloride and insulin. The dextrose appears to excite a production of insulin in addition to that which is injected. The insulin acts on the blood sugar and the proteolysis. Thus the glycogen reserve in the liver is maintained.

In the discussion Fredet called attention to the work of Roscher, published in 1933, in which the author found that after ether or ethyl chloride anesthesia an increase of from 50 to 80 per cent of the normal blood sugar occurs. There is only a slight hyperglycemia following spinal anesthesia and none at all when local anesthesia is employed. Two theories have been proposed to explain this hyperglycemia when volatile anesthetics are employed: (a) an excessive mobilization of the glycogen reserves of the body and (b) an increased oxidation in the tissues. A diminution of the glycogen reserve of the liver has been observed in all the cases following the use of ether or ethyl chloride.

Complete Auriculoventricular Dissociation

At the March 13 meeting of the Société médicale des hôpitaux of Paris Saulie Cattani and Bachmann reported the case of a woman aged 71 who had been treated for recurrent attacks of vertigo less frequently of syncope, accompanied by bradycardia (pulse from 28 to 32) since 1931. At the time of admission in 1935 the pulse was 40 and the blood pressure 300 systolic 140 diastolic. Electrocardiography revealed a complete auriculoventricular dissociation without notable deformity of the ventricular complex. At intervals an auricular fibrillation appeared which persisted during two or three at times even ten cardiac cycles and then the dissociation recurred. The particular feature of this rare case is the paroxysmal character of the auricular flutter. The authors could not find a similar reported case. The prognosis of these

cases of complete block with flutter presents great difficulty, especially if, as in this case, there is an accompanying hypertension.

The Frei Test in Lymphogranuloma

Frei of Breslau found in 1925 that pus from a case of lymphogranuloma had antigenic properties and hence could be employed in the form of a skin test to detect a specific cutaneous allergy in individuals who had a lymphogranulomatosis in the past or were still infected with the virus of the Nicolas Favre disease. Doubt arose as to the value of the Frei reaction when Clement-Simon, Braley and Minck in 1935 reported that in fifty prostitutes taken at random the skin test was positive in 8 per cent who did not present any evidence of having Nicolas Favre disease. Other dermatologists have had a similar experience but the percentage was much lower. Kleeberg was one of the first to show that a positive Frei reaction could be found in carriers of the virus of lymphogranuloma. In addition, the skin sensibility persists for a long time in persons who have had the disease, hence it would not be unusual for prostitutes to be either carriers or apparently cured individuals.

In order to study the question further as to the reliability of the Frei test, Escher and Chaglassian, two dermatologists at the faculty of the American College at Beyrouth, Syria, examined eighty-one prostitutes admitted to the venereal disease service of the Beyrouth hospital, for gonorrhea, cervical erosions and syphilis in the course of treatment. None of these had any discernible signs of the presence of Nicolas-Favre disease. With the exception of one case, the skin reaction in all of the eighty was negative. In this single case, a slightly infiltrated papule appeared which persisted for four days and which, other tests showed, was a doubtful reaction.

In their paper, presented by Levaditi at the April 21 meeting of the Academy of Medicine of Paris, Escher and Chaglassian stated that the Frei reaction can be considered positive only if a papule with a red dome and surrounding infiltration at 4 to 5 mm appears, which persists for eight to ten days. Even if the doubtful case is included, the reaction was positive in only 1.02 per cent of eighty-one prostitutes chosen at random and not presenting any evidence of the present or past history of having had Nicolas-Favre disease or lymphogranuloma.

Pancreatic Lithiasis and Diabetes

Pancreatic lesions have been the subject of a number of papers at meetings of various Paris societies. Marcel Labbé read a paper March 20 before the Société médicale des hôpitaux in which he stated that pancreatic lithiasis is rare and is associated with diabetes in a third of the cases. Labbé's recent patient was a man, aged 32, who in 1928 had severe pain in the right side of the abdomen accompanied by vomiting but no rise of temperature. A diagnosis of biliary colic had been made. Several similar attacks occurred the following year, but in one of these the pain was referred to the left lumbar region. In 1930 a very severe attack of pain accompanied by jaundice of a week's duration was noted. Following this attack the patient began to lose weight. This continued for the next two years. In 1932 he had a severe attack of pain accompanied by high temperature but no jaundice, and a marked glycosuria was found. In 1933 this condition was noted again, but no further attacks occurred until 1934. From this time on until first seen the attacks of pain recurred more frequently. Labbé in July 1934 found a polyuria (3,000 cc.), a glycosuria of 241 Gm and an x-ray shadow the size of a small olive over the head of the pancreas. A hyperglycemia persisted in spite of diet and insulin, accompanied by marked emaciation and fever of a non-remittent type. At operation by Lardennois a calculus 11 mm. in length was removed through an incision over the anterior surface of the head of the pancreas. The patient died three days after the operation.

A second case was cited in which the two conditions (lithiasis and diabetes) were associated, the patient dying of a pulmonary tuberculosis. At necropsy an atrophic sclerosis and numerous pea-sized calculi in all parts of the pancreas were found.

Labbé stated that the chief clinical features of a pancreatic lithiasis associated with diabetes are (a) the pain, usually referred to the epigastric and left hypochondriac regions, (b) symptoms due to absence of pancreatic digestion such as fatty stools and diminution of the pancreatic ferments in the secretion obtained with the duodenal tube, (c) the shadows of the calculi and (d) the diabetes.

Excess of Deaths Over Births

The "provisional" statistics for 1935 as reported from the ninety departments of France show that the number of deaths exceeded the number of births in the year 1935. There were 298,192 marriages in 1934 and 284,604 in 1935. As to births, there were 677,365 in 1934 as compared to 638,881 in 1935. The number of deaths was 634,525 in 1934 and 658,357 in 1935. The natality, i. e., the excess of births over deaths, showed a plus figure of 42,840 in 1934 and a minus figure of 19,476 in 1935.

The Place of Nonspecifics in the Treatment of Syphilis

An extensive discussion developed not long ago in the Hamburg Medical Society between Mulzer, professor of venereology, and Nonne, professor of neurology. Mulzer said that recent syphilis can virtually always be cured by specific chemotherapy, assuming that treatment is timely and energetic. Cases of long standing are not likely to respond to chemotherapy alone, but when it is supplemented by certain nonspecific measures favorable results may be achieved. It is well known too that stubborn cases in which the Wassermann reaction and changes in the cerebrospinal fluid have remained positive over a number of years occasionally show favorable response to heterogeneous nonspecific influences. Not one of the nonspecific methods, however, is reliable enough to permit of systematic application. Only two such procedures have given satisfactory results in cases of persistent positive Wassermann reaction and fluid changes that no longer respond to the ordinary therapy. The first is malariotherapy, which may be combined with the customary chemotherapy without interrupting it. Malariotherapy is superior to the substitute methods formerly recommended in its stead. Nevertheless Mulzer is now, as before, striving to perfect analogous procedures involving febrifacient vaccines. In his characteristic manner, Mulzer completely rejects the drugless methods of so-called Nature Medicine when applied to the treatment of syphilis, he has tested the most various procedures of "Nature Medicine" without obtaining any favorable results whatever.

The remarks of the neurologist Professor Nonne furnished an interesting pendant to the foregoing. He reported several atypical cases of hereditary syphilis in the second and third generations, which wandered completely away from the orthodox of the textbooks. In his forty six years of research, Nonne was able to determine numerous cases in which permanent cures of primary and secondary syphilis were effected without resort to or after quite inadequate treatment with anti-syphilitics. The patients usually came of healthy resistant stock and had acquired the infection at a youthful and vigorous age. Nonne also found that in hundreds of cases tabes and paralysis develop even when the patient has undergone intensive or at least not insufficient treatment. The importance of the individual constitution has long been recognized in the treatment of syphilis. It is an old proposition, too, that mercury and iodine are not specific remedies but rather function as alternatives

which prepare the way for better therapeutic action by the organism itself. In cerebrospinal syphilis the so called anti-syphilitics are of value only if the disease is of the gummosis type. This type however, according to Nonne's investigation, has become a rarity in recent decades. Tabes also is today less frequent, a fact confirmed by other authors, but the same certainly cannot be said of paralysis. Nonne does not consider it proved that syphilis is 100 per cent curable if energetically and properly attacked in its seronegative stage, he has observed a number of cases in which, on the basis of the foregoing concept, a marriage license was granted and subsequently both wife and children were infected with syphilis.

Of further interest were the points raised by Professor Mulzer in his concluding remarks. He emphasized that under no circumstances is treatment by injection indicated. If permanent cure is to be effected, a rigorous course of therapy must be instituted, one based on administration of the most powerful medicaments available, namely, arsphenamine and compounds of bismuth. In the treatment with arsphenamine, the administration of subtherapeutic doses is inadvisable. The greater incidence of neurorelapse in former times is attributable to inadequate treatment. Today, as the result of intensive treatment of early syphilis, neurorelapse has become quite a rarity. It is important that all syphilitic patients undergo Quincke's puncture every year or so according to the degree of infection present. The results of these tests should serve as an indication in questions of whether or not a patient should marry. Scruples against lumbar puncture are nowadays baseless, trouble is hardly ever encountered if the proper cannula is used. The appearance of a mercurial or arsphenamine dermatitis exerts virtually no influence on the subsequent course of the disease. Mulzer expressly warns that a positive Wassermann reaction should be regarded more or less as a "physical defect" and hence should be lightly evaluated. Thus Mulzer holds the opposite of the opinion that a positive Wassermann reaction is a certain indication of an active or latent syphilis which is likely to "unmask" itself at any time. The attempt should be made to make the positive reaction in the blood serum disappear by nonspecific means rather than by fruitless chemotherapy procedures. The combined use of arsphenamine treatment and malariotherapy is at present the only method of this nature that can be called reliable.

New Data on the Origin of Man

Hans Weinert, anthropologist, recently pointed out to the medical society in Kiel that data concerning the origin of man, already in the possession of specialized science, have yet to become common knowledge. Although the original views of Darwin and of Haeckel based on the so-called descent from the apes have in many respects undergone revision and expansion, the assertion that science should reject as false this earlier theory of the evolutionary process is out of the question. Within the great order of Primates the anthropoid apes occupy a wholly unique place full of amazing significance for the natural history of the human race. Weinert described the results of investigations in the spheres of comparative anatomy and physiology, this material represented in part data that have been available for some time although not well known. In the light of present day theories of heredity it would appear certain that among the anthropoid apes the orang-utan must figure prominently in evolutionary history, since this species, if the results of recent investigations are to be credited, occupies a place much nearer the lower apes than to the anthropoid gorilla and chimpanzee. The two latter African anthropoids possess in their turn so many inherited characters similar to the human as to point to a common relationship. In 1932 Weinert classified the three species gorilla-chimpanzee-man together as Sumnoprimates, namely, the most highly developed of the

Primates Then within this suborder of Summoprimates differentiation of characters was determined among all three species (the two apes and man) which seemed to place the chimpanzee nearer to man than to the other anthropoid apes. Weinert condenses his conclusion, or "anthropopithecus theory," as follows: "There remains extant today an animal species that possesses several inherited characters in common, not with other animals, but with our own human kind. This species is the African chimpanzee. This is not saying we are descended from chimpanzees but it does mean that there once was an ape-man species the descendants of which still exist today in the chimpanzee and in man, while all other existing species of anthropoid apes became differentiated from this intermediate type at an earlier date and hence fail to exhibit today the chimpanzee-human characters." It is certain that such a species existed at one time but it is impossible to state whether it constituted a race of anthropoid apes or was already a race of ape-men.

The Elimination and Accumulation of Digitalis Glucosides

Professor Lendle of the University Institute of Pharmacology lately discussed before the Berlin Medical Society a new method of testing the volumetric determination of elimination and accumulation of digitalis glucosides. By a procedure of his own device which makes use of "critical infusion velocity" it was possible to determine the amount of glucoside detoxicated by the organism per kilogram and per unit of time. In rabbits this value amounted per hour to 20 per cent of the lethal dose of g-strophanthin and digitoxin. In other animals, different values were determined both in general and for individual glucosides. In his investigations of the tendency to accumulate Lendle used a combination of the methods of Fränkl and Hatcher. For seven days cats were subjected to small dosages of glucoside subcutaneously injected, on the seventh day the effective residuum of the administered glucoside still present in the organism was determined by titration of the 'full lethal dose.' This means that an amount of the glucoside in question was injected sufficient to cause the death of the animal, and this amount compared with what would normally constitute a lethal dose. Cumulative after-effects still showed themselves in these experiments when 3 per cent of the lethal dose of digitoxin was administered daily. A daily injection of 75 per cent of the lethal dose of k-strophanthin produced similar results. An increase in the daily dosages caused a constant corresponding rise in the cumulative effect, and the accumulation thus attained a higher value as it generally corresponded to the sum of the partial doses administered. Accumulation cannot therefore be considered as merely a chemical storing up. Since injuries to the heart muscle could not with certainty be histologically determined in these cases, such lesions cannot be considered as a cause of the cumulative effect. This demonstration of the intensified effect by distribution of the dosage over a number of days justifies the assumption that the cumulative effect of digitalis is not connected with the phenomena of concentration alone but belongs rather with those of the allopathically acting substances. Accordingly the accumulation should no longer be considered solely from the toxicologic point of view but as a prerequisite to uniform digitalization as well especially if treatment is to be carried on for a considerable period.

The Dental Physicians' Campaign Against the 'Dentists'

The fight waged by the dental physicians (zahnärzte) against the dental technicians the so-called dentists (dentisten) has been mentioned previously (THE JOURNAL, May 18, 1935, p. 1837). A few days ago a conference to discuss more effective organization among dental physicians and better means

of extending their practice was held at the ministry of the interior. This is significant. The "dentists," who as a class possess no scientific preparatory training, are able to work for less remuneration than the dental physicians and moreover are not amenable to a licensing control. The national fuhrer of dental physicians accordingly demands the institution of a numerus clausus and a division of the reich into "dental physician districts." The "young dental physicians" will be requested to engage in country practice for from five to seven years before settling in the cities. How successful this offensive of the dental physicians will be is difficult to predict, since among the poorer classes there exists considerable sentiment in favor of the 'dentists,' and the National Socialist party, which certainly is in sympathy with the Nature Cure movement, could readily apply to the dental physician question the party's frequently skeptical attitude toward the exclusiveness of scientifically trained medical men.

Of further interest are the likewise recent arguments of the national fuhrer of dental physicians before the dental physicians of Berlin. Dental caries is at present the fourth most common of diseases. Yet the campaign against this disease is being obstructed by this assumption of the professional function of the dental physicians by the "dentists" and is further complicated by the inadequate preparatory training of the latter group. A comprehensive program of dental hygiene for children can be carried out only by one single closed professional group the members of which conceive of their calling not as a means to pecuniary gain but as a mission of service in the interest of the German national health. A modern dental physician must be concerned not only with a tooth to be filled but with the diseased surroundings as well. Another important task is to be the standardization of the training and professional status of the dental physician. The success of these endeavors remains doubtful in view of the tendency dominant in Germany at present to prefer more or less paramedical methods and practitioners.

JAPAN

(From Our Regular Correspondent)

May 20, 1936.

Children with Poor Vision

Not until 1932 did the Tokyo municipal officials, for the first time, undertake to investigate the vision of school children. In the following year the first eyesight class was attached to a certain primary school on a small scale. The so-called poor vision in this country means vision that cannot be improved by any glasses. The Ophthalmic Association of Japan has defined it as follows: Children with poor vision of low degree are those who cannot see clearly even with the aid of glasses; the 0.3 in the international vision test chart, while children with a higher degree are those who can barely discern figures 1 meter distant. They are divided into two classes, A and B. Class A contains those who, with glasses, cannot clearly see the 0.3 in the international chart and can discern figures 2 meters distant. Class B includes those who, with the aid of glasses, cannot discern figures 2 meters distant. The Education Office ordered the local government to examine the vision of school children throughout the country last year. Among 3,740,215 boys and 3,625,813 girls examined they found 4,257 boys (1.25 per thousand) and 5,237 girls (1.44 per thousand) with poor vision. These figures contain 4,258 boys of class A and 4,765 girls of class B. The number of children who were allowed to postpone entering the primary school on account of poor vision was 114 forty-seven of whom were boys and sixty-seven girls. The number with poor vision increases as the school year advances. There are, for instance in the sixth year class which is the highest grade in the first primary course, more than three times as many with poor vision as in

the first year class Generally speaking, there are more weak-sighted girls than boys The causes of poor vision are first those of hereditary nature, then comes trachoma, then near-sightedness of high degree, and finally physical weakness Several classes for poor children with defective vision are to be established in Tokyo and in other great cities in the near future

Diabetes in the Japanese

In the thirty-third general meeting of the Society of Internal Medicine of Japan, April 1, in Tokyo, Prof Dr Kozo Sakaguchi of the Tokyo Imperial University read a paper on glycosuria and diabetes in the Japanese While in this country some research workers report that diabetes is on the increase, those statistics are all derived from the results of examination of patients in the larger hospitals in great cities Generally speaking, the Japanese have a milder attack of diabetes than do Europeans or Americans Consequently, most of the patients are unaware of their condition until they are forced to have their urine examined on account of some other sickness Thus reports of an increase in this disease must be well analyzed before it is believed It has much to do with the number of urine examinations, which were made less often formerly, while nowadays all practitioners make more examinations of urine The number of insured persons was only a little over 1,000 in 1881, but they numbered more than 8,000,000 in 1932 The physical examination made on application for insurance often reveals diabetes, to the applicant's surprise It may safely be said that diabetes in Japan is not showing a tendency to increase.

Semicentennial of Issue of Japanese Pharmacopoeia

The semicentennial of the issue of the Japanese pharmacopoeia was celebrated April 13 in Tokyo under the joint auspices of the Japan Pharmacology Society, the Japan Pharmacutists Association, and the four guilds of drug manufacturers Prof Dr K. Keimatsu of the Tokyo Imperial University acted as chairman.

Prizes Awarded

The Imperial Academy at a general meeting awarded its Imperial Gift for 1935 to Dr Takaoki Sasaki, the chief of the research section of the Kyoundo Hospital, and Dr Tomizo Yoshida, assistant professor in the Nagasaki Medical College, in recognition of their achievements in producing tumors The Academic Prize was awarded to Prof Dr Masaji Tomita of the Taiwan Medical College in recognition of his researches on the metabolism of an embryo Prof Dr Michizo Asano of the Nagasaki Medical College is to be given the same prize in recognition of his research on fatty acids

Professor Mita Retires

Prof Dr Sadanori Mita of the Tokyo Imperial University has reached the age limit and has retired He entered the medical college of the university as a student in 1897 Graduating with honors in 1901, he was appointed an assistant in the department of medical chemistry under the late Dr Kumagawa He was transferred to the department of legal medicine in 1904 In 1907 he was ordered abroad and went to Germany and France for three years Returning home he was awarded the highest title as a doctor, the "Igaku-Hakushu" In 1918 he was promoted to professor and held the chair of serologic chemistry, in 1924, when Dr Katayama retired, he held the chair of legal medicine as well For more than thirty years he devoted himself wholly to this university He turned out more than 250 doctors under his tuition All of the chairs in the departments of legal medicine in any medical university in this country are occupied by his followers He is expected to go to the Taiwan Imperial University as dean He is to be succeeded by Prof Dr S Furuhashi of the Kanazawa Medical College, who is one of his most prominent followers

Marriages

PERRY SANBORN BOYNTON JR, New York, to Miss Mary Ellen Heiss of East Orange, N J, June 13

WILLIAM DAVIS, Elyria, Ohio, to Miss Dorothy Garrett of New York, in Crestline, Ohio, June 20

THOMAS D ARMSTRONG Rochester, Minn, to Miss Isabel Foster of Shelbyville, Ill, June 4

ROBERT E DOWNING, Terre Haute, Ind, to Miss Mildred Pinnell of Kansas, Ill, June 10

GUY WINSTON HORSLEY, Richmond, Va, to Miss Mary Clare Wright in Petersburg, June 10

GURNEY TAYLOR New York, to Miss Renee Brebion of Greenwich, Conn, June 13

ALBERT S BACON, Albany, Ga, to Miss Sarah McLedon of Atlanta in Griffin, June 14

CHARLES ALLISON, Kankakee, Ill, to Miss Harriett Rossi of Braidwood, recently

HOWARD T WHITE, Stapleton, N Y, to Miss Helen Marjorie Terry, June 23

Deaths

Henry Sewall ♂ professor of medicine, emeritus, University of Colorado School of Medicine, Denver, died July 8 of coronary thrombosis with infarct and terminal cardiac rupture, aged 81 A native of Winchester, Va Dr Sewall received the degree of doctor of philosophy in 1879 at Johns Hopkins University, Baltimore, where he taught biology from 1876 to 1881 In 1882 he went to the University of Michigan Department of Medicine and Surgery as professor of physiology In 1889 he received the degree of doctor of medicine from the University of Denver Medical Department and was professor of physiology from 1890 to 1908 He became professor of medicine at the University of Colorado School of Medicine in 1911 and professor emeritus in 1920 Dr Sewall served as assistant health commissioner of Denver from 1891 to 1893 and for the next six years as secretary of the Colorado State Board of Health, and from 1915 to 1919 as a member of the National Board of Medical Examiners He had been president of the Medical Society of the City and County of Denver (1916), the Colorado State Medical Society (1924), Denver Academy of Medicine (1903-1905), American Climatological Society (1915) Association of American Physicians (1916) and the National Tuberculosis Association (1927) In 1930 the National Tuberculosis Association presented to him the Trudeau Medal and in 1931 he received the medal awarded by the Kober Foundation through the Association of American Physicians The University of Michigan conferred on Dr Sewall an honorary degree of doctor of medicine in 1888 and of doctor of science in 1912, Wesleyan University conferred on him the degree of doctor of science in 1926 and the University of Colorado in 1927 He was a member of the editorial board of the *American Review of Tuberculosis* from its inception in 1917 until his death, was the author of many articles on tuberculosis, immunology and clinical medicine and from its establishment in 1919 was a member of the research advisory board and an active investigator in the research department of the National Jewish Hospital, Denver

Alden Humphrey Williams, Grand Rapids, Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899, fellow of the American College of Physicians member and past president of the Radiological Society of North America, past president of the Kent County Medical Society member of the staff of the Blodgett Memorial Hospital and Butterworth Hospital aged 58, died, June 10, of coronary occlusion

John Monroe Sigman, Macon, Ga, University of Georgia Medical Department, Augusta, 1904 member of the Medical Association of Georgia, served during the World War for many years a national guard officer, on the staff of the Macon Hospital aged 55, died, April 10 in the Veterans Administration Facility Atlanta, of an infection of the leg complicating diabetes mellitus

Harry Montrose Slade, Reisterstown, Md, University of Maryland School of Medicine, Baltimore, 1884 member of the Medical and Chirurgical Faculty of Maryland, county health officer from 1912 to 1924 district health officer from 1901 to 1926, aged 74, died April 15, in the Maryland General Hospital, Baltimore, of arteriosclerotic heart disease

Walter Klingeman Long ⊕ Hampton Iowa, Northwestern University Medical School Chicago 1906, formerly secretary of the Franklin County Medical Society, served during the World War, director of the laboratory and x-ray department of the Lutheran Hospital, aged 60, died, April 3, of pneumonia and abscess of the liver

Edwin Clyde Morgan ⊕ Clay Center Kan, Northwestern University Medical School, Chicago, 1910, formerly secretary of the Clay County Medical Society, member of the Kansas Board of Registration and Examination, served during the World War, aged 51, died, April 27, of chronic myocarditis and nephritis

David Hirst Mills ⊕ Oneonta, N Y University and Bellevue Hospital Medical College, New York, 1911, past president of the Otsego County Medical Society, served during the World War, on the staff of the Aurelia Osborn Fox Memorial Hospital, aged 50, died, April 15, of coronary embolism and acute tonsillitis

William Turner Van Pelt ⊕ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1885 served during the World War, aged 71, formerly on the staffs of the Episcopal Hospital Wills Hospital and St Joseph's Hospital, member of the board of managers of the Chestnut Hill Hospital, where he died, April 26, of heart disease

Andrew James McGraw, Taunton, Mass, College of Physicians and Surgeons, Baltimore, 1906, member of the Massachusetts Medical Society, for many years mayor of Taunton, for twelve years a member of the school committee, served during the World War, aged 54, died April 20

Edwin Seymour Miller, Flagstaff, Ariz, University of Buffalo School of Medicine, 1879, served for a time as county health officer and as head of the city municipal health department for many years local surgeon for the Atchison, Topeka and Santa Fe Railroad, aged 78, died, April 29

Albert Edwin White, Houston, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1908, member of the State Medical Association of Texas, served during the World War, aged 54, died, April 12, in St Joseph's Infirmary, of cerebral thrombosis

S T D Lancaster, Spartanburg S C, Medical College of South Carolina, Charleston, 1879, member of the South Carolina Medical Association, for many years a member of the state legislature, aged 78, died, April 27, in the Mary Black Hospital, of pneumonia

Charles Henry Lefcoe, Philadelphia, Jefferson Medical College of Philadelphia, 1897 at one time associate in pediatrics and instructor and demonstrator in clinical medicine at his alma mater, aged 60, died, April 4, of coronary thrombosis and pulmonary edema.

William Homan Roe ⊕ Patchogue, N Y, College of Physicians and Surgeons, Medical Department of Columbia College New York, 1894, for many years health officer of the town of Brookhaven, aged 65, died, April 14, of arteriosclerosis and heart disease.

John Patrick Lenahan, Bellows Falls, Vt, University of Vermont College of Medicine Burlington, 1902 member of the Vermont State Medical Society, member of the school board aged 58 died April 2, of complications following an operation for appendicitis

William E Washburn, Kewanee, Ill., Hospital College of Medicine Louisville, Ky, 1899, member of the Illinois State Medical Society aged 65 on the staffs of St Francis Hospital and the Kewanee Public Hospital, where he died April 27, of pneumonia.

James Holland McCorkle, Gordon Texas University of Tennessee Medical Department Nashville, 1880 member of the State Medical Association of Texas past president of the Palo Pinto County Medical Society, aged 80, died April 17, of pneumonia.

John Calhoun Marshall, Checotah Okla Medico-Chirurgical College of Kansas City Mo 1904 member of the Oklahoma State Medical Association past president of the McIntosh County Medical Society aged 52, died April 11, of chronic nephritis

Charles Storer Knight Portland Me. Harvard University Medical School Boston 1896 member of the Maine Medical Association on the staff of St Barnabas Hospital and the Farrington Hospital, aged 63 died April 12 of cancer of the stomach.

John Bates Lyon, River Forest Ill Rush Medical College Chicago 1901 on the staff of the Garfield Park Hospital Chi-

cago, formerly on the staff of the Oak Park (Ill) Hospital, aged 56, died, April 24, of carcinoma of the lungs and of the cheek

George Walter Lewis, Belle Vernon, Pa, Jefferson Medical College of Philadelphia, 1917, served during the World War, aged 42, died, April 2, in the McKeesport (Pa) Hospital of sinus infection, otitis media and rheumatic fever

George U Lipshulch, Oak Park, Ill, National Medical University, Chicago, 1906, served during the World War, formerly member of the state legislature, aged 55, died suddenly, April 7, in Chicago, of coronary thrombosis

Robert Lee McWhorter, Gaylesville, Ala Medical College of Alabama, Mobile, 1887, member of the Medical Association of the State of Alabama, aged 71 died, April 5, in a hospital at Rome, Ga., of bronchopneumonia

Edward Johnson Logan ⊕ Providence, R I, Jefferson Medical College of Philadelphia, 1903, on the staffs of St Joseph's and Homeopathic hospitals, aged 67, died, April 8, of chronic myocarditis and chronic nephritis

Adalbert Alexander Vass ⊕ Richmond Hill, N Y, Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1912, on the staff of the Wickersham Hospital, New York, aged 47, died, April 26

Michael Joseph Maguire ⊕ Yakima, Wash St Louis University School of Medicine, 1913, aged 52, died April 13, in St. Vincent's Hospital, Portland, Ore, of bronchial asthma, pulmonary edema and cardiac dilatation

Franklin A Marsh, Alameda, Calif, State University of Iowa College of Homeopathic Medicine, Iowa City, 1889, member of the Idaho State Medical Association, aged 79, died, April 1, of uremia and arteriosclerosis

John Stanislaus Kelly, Quincy, Mass, Middlesex College of Medicine and Surgery, Cambridge 1921, aged 49, died, April 20 in the City Hospital, Boston, of injuries received when he was struck by an automobile.

John A McLeod, Brooklyn, Long Island College Hospital Brooklyn, 1889, member of the Medical Society of the State of New York, aged 76, died, April 7, in the Long Island College Hospital, of heart disease

James Matthias Kibler, Newberry, S C, University of Maryland School of Medicine, Baltimore, 1886 member of the South Carolina Medical Association, aged 76, died, April 19, of chronic nephritis

William Thomas Sellers, Mobile, Ala, Tulane University of Louisiana School of Medicine, New Orleans, 1933, aged 26, died, April 27, in the United States Naval Hospital, Pensacola Fla, of pneumonia

George Philip Shirmer, Mount Vernon, N Y, Bellevue Hospital Medical College, 1873, aged 83, died April 10 in the Mount Vernon Hospital, of injuries received when he was struck by an automobile.

Moses Joseph Konikow, Brookline, Mass Universität Bern Medizinische Fakultät, Bern, Switzerland 1893, member of the Massachusetts Medical Society, aged 68, hanged himself, April 26

Francis Cassat Warne, Chicago, Northwestern University Medical School, Chicago, 1893, formerly a surgeon for the Illinois Central Railroad, aged 77, died, April 18, of cerebral hemorrhage.

George McCulloch, Humeston, Iowa, Rush Medical College, Chicago, 1873 formerly member of the state legislature for many years bank president, aged 87, died, April 12, of pneumonia

Charles Louis McEveety, New York, Long Island College Hospital, Brooklyn, 1909, aged 49, formerly roentgenologist at the Union Hospital, where he died, April 22 of pneumonia

William W Mitchell, Greenfield Tenn University of Tennessee Medical Department, Nashville, 1898, aged 73 died April 1, at the Methodist Hospital, Memphis of Parkinson's disease.

Edward Mark Russell, Springfield Mass McGill University Faculty of Medicine Montreal Que, 1901 aged 67, died April 21, in the Mercy Hospital, of acute appendicitis

Stephen McReynolds, Terrell Texas Vanderbilt University School of Medicine, Nashville Tenn 1884 aged 76 died suddenly, April 10 of coronary thrombosis

Julius Wesselowski ⊕ Jewell Kan University Medical College of Kansas City, Mo, 1885 aged 78 died April 17 of coronary occlusion

Correspondence

DISLOCATIONS OF KNEE JOINT

To the Editor—Under Correspondence in *THE JOURNAL*, May 9 page 1679, we note the comments of Dr Fichman on our article entitled "Dislocations of the Knee Joint" (*THE JOURNAL*, April 11, p 1252)

Dr Fichman states that our statement that "the records of many large hospitals failed to show a single case of a complete dislocation of the knee" is not in accord with the surgical literature. In answer to this we quote from Dr Fichman's own article on "Dislocations of the Knee Joint" (*THE JOURNAL*, Oct 5, 1935, p 1111), wherein he quoted the following: "Dr Ritter failed to find a single case of a dislocated knee among 23 000 accident cases at the Reconstruction Hospital." In an extensive review of the literature on dislocations of the knee we find that many articles begin with the statement as to the rarity of this condition. It was not our entire purpose to assume that we were reporting an unusual condition when we reported this case of a complete lateral dislocation of the knee but to emphasize certain important procedures in the postoperative care.

We are sure Dr Fichman did not intend to leave one with the impression that the procedure of reduction which he used was original, because such procedure, to our knowledge, has been used for many years. Besides, our patient was admitted to the hospital and reduction done Nov 1, 1934, over two months before Dr Fichman's case was first seen by him.

Our treatment was different from Dr Fichman's as regards immobilization. We applied a hip spica for six weeks while in Dr Fichman's case immobilization was done only in a posterior splint for ten days, when it was removed at intervals for active motion. Functional improvement in our case has taken place since the publication of our article, especially flexion of the leg at the knee. We want to congratulate Dr Fichman on his patient's excellent functional results.

We wish to emphasize again that having a photograph of our patient before reduction was unique. We have not, as stated in our article, found in the literature a photograph of a lateral displacement of the knee joint previous to reduction. It is not out of the ordinary that the roentgenogram in our case should be similar to Dr Fichman's because most complete lateral dislocations of the knee joint, as well as all other complete dislocations of the knee joint, have marked similarity, so far as x-ray observations are concerned.

Owing to the fact that space prevented the full publication of our bibliography in *THE JOURNAL* it was unfortunate that Dr Fichman's article was not referred to. Reference to his report does appear in the reprints of our article, however.

EXPERT GARGLING

To the Editor—Gargling with colored fluids, as suggested by Dr Walker of England in *THE JOURNAL*, June 27, page 2253, will readily prove that, to gargle well the person should first swallow the fluid he is about to gargle with the mouth wide open, head well back and then gargle it around as is the usual practice, as long as his breath will permit, he can reach thus the entire posterior pharyngeal surfaces. If his mouth is wide open when he swallows, the fluid cannot go down below the pharynx. If it does, the mouth must have closed in some way. Furthermore, if the gargler while letting the air bubble up through the fluids in his throat, making that melodious sound

of a babbling brook in a great hurry, will allow the air to go through his nose instead of his wide open mouth, and at the same time nod his head forward as he spits the fluid out, some of the fluid will readily come out through the nose. Thus he will reach mouth, pharynx, nasopharynx and accessible parts of the nose, all by one comprehensive act.

HENRY L SWAIN, M D, New Haven, Conn

AIR-TIGHT JOINT IN ANESTHETIC MASK

To the Editor—Anesthetists who use Dr Ralph Waters' closed soda lime absorption technic have been plagued by the tendency of most masks to leak between the rubber rim and the body as soon as slight stretching of the rubber has occurred. I have tried various things to achieve an air-tight joint, from sections of inner tubing to folded adhesive tape. The latter is the most successful but has obvious disadvantages. A device more sanitary and almost as effective is a couple of curved half inch strips of blotting paper slipped between the rubber rim and the celluloid or metal body, and moistened with water.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

DERMATITIS IN BANANA INDUSTRY

To the Editor—Can you give me any information regarding a dermatitis in individuals who are handling bananas caused by contact either with the outer skin or the juices or the combination of these factors?

HARRY L BAEZ, M D, Pittsburgh

ANSWER.—A contact dermatitis from the uncontaminated pulp of the banana almost invariably is of allergic nature. The sensitizing agent leading to the allergic dermatitis may be different in the skin and in the pulp. Allergic manifestations from fruit are preeminently related to the skin. Patch tests with small portions of the banana pulp or the banana peel may be applied to establish the actuality of an allergic state.

Bananas are likely to harbor various forms of fungi. During the period of growth, various insecticides and disinfectants may be applied to the banana tree. Arsenical mixtures are in some use, as are also phenolic solutions. Conceivably the presence of such agents might account for a contact dermatitis when the skin of the worker touches the banana stalk or rinds. At the present time various gases are being used for the artificial ripening of bananas. There is no proof that these gases or vapors are productive of any skin diseases, but the possibility exists. One cause of dermatitis among banana handlers is the coarse twine made of jute, used for hanging the banana bunch. A jute dermatitis is a well known minor disease entity.

In the case of almost all fruit handling on a commercial scale industrial skin diseases may arise. This fact has given rise to the general term "fruit dermatitis." This term embraces a number of unrelated types of the skin disorders, some from yeasts and fungi, others from germicides and insecticides, and still others from waxes sometimes utilized in the preservation of natural fruits. Mention is now made of two reported occurrences of fruit dermatitis. Mackay and Ireland (Investigation into the Fruit Industry Health Bulletin Victoria, Australia, July-September 1928, p 481, abstr *J Indust Hyg* 11 164, 1929) have found that various forms of skin diseases exist among the handlers of peaches, lemons and crystallized fruits. Kingery and Thienes (Mycotic Paronychia and Dermatitis, *Arch Dermat & Syph* 11 186 [Feb] 1925), in investigating an epidemic of fruit dermatitis, encountered yeasts which when cultured led to a similar dermatitis when applied to the skin of animals and nonexposed workers. These authors concluded that at least certain forms of fruit dermatitis may be classed as dermatomycoses.

TREATMENT OF ACROMEGALY

To the Editor—Please give me any information you have on the present treatment of acromegaly. The patient in question is approximately 50 years old. The roentgenogram of the sella was negative and there were no changes in the visual fields. The main indication of change in the pituitary gland is exhibited in the change in the form and size of the extremities and the facial expression. The metabolic rate was -3 . The general physical condition was negative except for some enlargement of the inguinal glands. The blood pressure was 130 systolic 100 diastolic. The patient was operated on at another institution for anal contraction, anal abscess and a fistula. From the latter operation he had apparently entirely recovered. Before coming to me he had amniotin injections which he thought gave him results for a time but he has discontinued this treatment because he is positive that it is not doing him good any longer. After coming to me his main symptom has been severe headaches occurring at forty-eight hour intervals coming on in the middle of the night or early in the morning and lasting until about noon. He also has been unable to sleep except for a few hours early in the morning. He has been nervous and fearful of the outlook. He has been told that if this disease is not arrested he will become blind. He has been advised at the hospital where he had the first examination and the rectal operation to return to that institution for a course of roentgen treatments. I have been able to reduce the patient's headache from forty-eight to ninety-six hour intervals and he has been sleeping better. What information can you give me on the possible success of a course of roentgen treatments? If you have any information of value can you tell me what dosage and at what intervals treatment is given? Have you any other suggestions as to treatment in this case? Please omit name.

M. D. Illinois

ANSWER—The treatment of acromegaly is still in its empirical phase, the object of which is to decrease the amount of pituitary secretion. This disease is often associated with other glandular disturbances, and for this reason a number of glandular extracts, such as thyroid and estrogenic preparations, have been administered for the specific purpose of reducing the activity of the pituitary gland. Unfortunately, no specific therapy has yet been determined. In some instances high-voltage roentgen therapy has been effective in controlling the symptoms, in other instances the patient has been subjected to a craniotomy and an intracapsular enucleation of the pituitary with the implantation of radon seeds into the capsule. The latter procedure has been most effective in controlling the growth of the anterior lobe and bringing about a cessation of symptoms. The intracranial approach is a major procedure and is rarely resorted to unless visual disturbances occur, and then by all means, an intracapsular enucleation should be employed in conjunction with the insertion of radon seeds.

FATIGUE AND BASAL METABOLIC RATE

To the Editor—I have a patient who manifests extreme fatigue. The only positive manifestation is a basal metabolic rate of -20 . There are no physical evidences of myxedema outside of a slight fullness of the thyroid. The physical examination and x-ray studies are essentially negative. Please discuss possibilities. Omit name. M. D. New York.

ANSWER—In the majority of cases in which there is a deviation from the normal of the basal metabolic rate, the thyroid gland is at fault. A rate as low as 20 per cent below normal is probably significant. A variation of 10 or 15 per cent above or below is usually considered the normal range. It may be that there is less normal variation below than above. The clinical symptoms and a careful evaluation of all the facts are necessary for diagnosis. The basal metabolic rate, while an important guide, is not of itself diagnostic and can be considered only in conjunction with other evidences of disorder.

Fatigue is a common complaint in hypothyroidism. In mild cases there may be no other finding than a depressed basal metabolism. In fact, many of the clinical symptoms are dependent on impaired heat production. Myxedema as a fully developed syndrome may not be present. Dry skin and hair, poor tolerance of cold, and tolerance of heat are significant. The patient is not comfortable at room temperatures that are not too low for other members of the family. The pulse is usually slow. These people tend to be sluggish both mentally and physically, but often the condition has continued for long periods and they are not conscious of their condition. These symptoms may not be present. Some thin individuals with low metabolism and fatigue have accelerated heart rates and yet improve on thyroid therapy. These cases may not actually be primary thyroid disorders even though they respond to thyroid administration.

In the case described the therapeutic result of carefully observed thyroid administration might be the final diagnostic criterion.

Other glandular disorders must be considered. Simmonds disease (pituitary cachexia) is characterized by low basal metabolism in addition to weakness, weight loss, dry skin, alopecia and aged appearance. Early in the course of the dis-

ease, these symptoms may not be fully developed. The advanced case of Addison's disease is easily identified, but early atypical examples may show only weakness, weight loss, hypotension and low metabolic rate.

That low basal metabolism is usual in inanition as well as in actual starvation cannot be doubted. This was amply demonstrated in central Europe during the World War and has been shown in famine studies elsewhere. Wasting, debilitating non-febrile diseases may show variations both above and below normal. In diabetes the rate is more often moderately depressed than elevated, except in acidosis.

It has been suggested that neurosis and anxiety states may present both fatigue and low metabolism, and even that fatigue resulting from overwork or insufficient sleep may lower the basal energy production.

SENSITIVITY TO ARSPHENAMINE

To the Editor—What can be used in the place of neoarsphenamine in a patient who has become sensitized to the drug? The reaction consists of prostration, fever, sweating, nausea and vomiting following within fifteen minutes to a half hour after administration. Care has been taken to use only double distilled water in sterile ampules, to use the solution immediately and to inject it slowly. Several different batches of the drug have been tried but all with the same result. The patient is a girl aged 19 years weighing about 120 pounds (54 Kg.). She presented herself for treatment at the appearance of a secondary rash. She also had alternate courses of bismuth solution in olive oil (twelve injections of 1 cc. intramuscularly) and 0.45 Gm. of neoarsphenamine (6 10 cc. of water). She had had about eighteen injections of neoarsphenamine when the trouble developed—in other words, three courses of the drug given at five day intervals. The drug was withdrawn immediately and she was kept on the bismuth preparation for an interval of six weeks after which three injections have been attempted but always with the same result. At present she shows no evidence that she has become saturated with the drug bismuth there being no evidence of a deposit in the mucous membranes and no primary manifestations to indicate renal damage. Please advise. Kindly omit name. M. D. Minnesota.

ANSWER—Some patients develop a definite intolerance for the type of arsphenamine they are receiving, so that by changing to another type the course may be completed satisfactorily. When patients become reactive to neoarsphenamine, the use of arsphenamine given slowly and well diluted may be well tolerated. Also the use of one of the brands of arsphenamine for intramuscular use might be tried. The danger of argyria from silver arsphenamine preparations is great enough to interdict its use. Occasionally by using a neoarsphenamine made by a different manufacturer, reactions of the type described can be avoided. The use of dextrose either by vein or by mouth previous to the injection may prevent such reactions, which must be looked on as forewarnings of intolerance to the drug, which may increase with each injection. If the patient is found to be reactive to several of the various types and brands of arsphenamine, it is then necessary to limit subsequent treatment to a bismuth or mercurial preparation.

USE OF DEXTROSE INTRAVENOUSLY IN SHOCK

To the Editor—I have noticed repeatedly drops in blood pressure following intravenous injections of dextrose. I know of course, that the percentage of the solution figures in this drop. I should like to have information concerning the treatment especially of shock with dextrose in other words the effect of intravenous dextrose on blood pressure according to solutions of various percentages also whether or not it is advisable in the treatment of shock, especially traumatic and postoperative shock. What other solution is preferable? What are the contraindications to the use of dextrose? Is it advisable to use insulin with dextrose regularly? J. E. STAFFILL, M.D. Jenkins Ky.

ANSWER—Whether a rise or a fall in blood pressure will occur following intravenous injection of dextrose depends on a number of factors. In the first place, excessively rapid injection of the solution produces what has been called speed shock (Hyman and Hirschfeld *THE JOURNAL* Feb 4 1933, p. 305). When dextrose is given at the proper rate, literally drop by drop this form of unfavorable reaction is prevented. When it is given by drip phlebotomy, the effect on the blood pressure is entirely dependent on the progress of the patient's condition rather than on the treatment. Aside from supplying water and sodium chloride—the latter is important and should be provided in the solution—during a state when there is a drain on the system without chance for replenishment through the ordinary channels, the dextrose may antagonize starvation, acidosis and that is all the good dextrose-saline solution can do in shock. As this is therefore merely a matter of replacement of nutritional essentials, it has no place in the early treatment of shock. Indeed this irksome procedure may aggravate the condition by its psychic trauma. When blood has been lost it may be of detriment rather than of advantage, as it is likely to lower still further the percentage of corpuscles in the circula-

lating blood This is one of the reasons why blood transfusion is so much more important in the treatment of shock, especially that following hemorrhage, than the infusion of any other kind of fluid When there has been a great loss of salt from the system, as by excessive emesis, hypertonic (10 per cent) sodium chloride solution may be the most important emergency remedy Hypertonic dextrose solution should be avoided, as it causes crenation and possible destruction of blood corpuscles when none can be spared, and it will still further increase the existing state of hypohydration of the tissues The employment of 7 per cent acacia solution in shock is still *sub judice* It has not made a place for itself in spite of recommendation by high authorities One should therefore employ drip phlebotomy, using equal parts of 5 per cent dextrose and 0.9 per cent sodium chloride solution, as the first offering of diet to a patient who is emerging from shock and who is presumably or actually in such a condition that he is not likely to benefit from the ingestion of fluid by mouth Excepting in a case of diabetes mellitus, insulin should be employed only when sugar appears in the urine of a patient who is given dextrose phlebotomy and then only in guarded dosage to make hypoglycemia impossible.

INDUSTRIAL HAZARD OF COPPER PLATING

To the Editor—I have a patient who is employed in electroplating copper After the plating the copper is dipped in a solution of two parts of sulfuric and one part of nitric acid He has been doing the work for three months exposed to the fumes of sulfur dioxide and nitrogen peroxide, which occur following the dipping process For the past ten days he has had nosebleeds and complains of a marked loss of appetite and energy The patient has a marked pallor of face and moderate pallor of the conjunctivae and of the mucous membranes of the mouth There are two ulcers on each side of the nasal septum The blood count is red blood cells 3,100,000 hemoglobin 60 per cent, white blood cells 9,200 polymorphonuclears 74 per cent, lymphocytes 26 per cent Will you kindly explain the action of these vapors and treatment of the condition? I would also be interested in literature on industrial hazards in copper plating following this dipping process. Kindly omit name

M D, New York.

ANSWER.—Granting that this condition is the result of exposure in electroplating and is not the result of extraneous causes, it is at once to be recognized that the atmosphere of a plating room may represent a complex mixture of gases vapors and mists Rarely is it true that only one type of plating is carried out in any given plant. Simultaneously plating operations may include nickel, cadmium, chromium, copper and, rarely, lead and zinc. In the preparation stage of the metal various acids, alkalis and cyanides may find application. Furthermore, both the metals and pickling agents may contain impurities A diagnosis of "mixed intoxication" becomes warranted at times in this industry Conceivably arsenic may be present, which in combination with the hydrogen produced in the plating process may lead to arsenureted hydrogen, whereupon an anemia may arise as part of the general chronic arsenic poisoning It is more likely that the anemia may be traced to the action of acids and alkalis together with heterogeneous agents on the teeth, the alimentary tract and the mucous membranes in general This may eventuate in damaged teeth, respiratory disease and digestive disturbances, to the end that a secondary anemia may appear

The ulceration of the nasal membranes and the nosebleed are ready results from almost any severe exposure to acid or alkali vapors Sulfur dioxide on contact with the membranes quickly is changed to sulfurous or sulfuric acid, and the oxides of nitrogen thus may become nitrous or nitric acid. Ulceration from cyanogen compounds also occurs

The problem of control of the abnormal states caused by such hazards chiefly is one of eliminating the exposure. Palliative treatment is almost worthless so long as exposure is perpetuated. Exhaust systems with lateral intakes at the edges of plating and pickling tanks are highly regarded for protective purposes in plating plants In some instances special metals may be required in the building of exhaust systems, since the life of ordinary sheet metal may be short when exposed to various alkalis and acids

If further physical examination of the patient leads to suspicion that arsenic may be the guilty agent, appropriate steps should be taken to prove the presence of arsenic in the work-room atmosphere or as an impurity of some used material

Extensive information on the hazards of plating may be found in the following standard publications

CONSTIPATION IN INFANCY

To the Editor—A child aged 22 months weighing 28 pounds (13 Kg) and measuring 34 inches (86 cm) has been having periodic digestive upsets ever since the eruption of his teeth when he was 5 months old He has sixteen teeth now He was a full term baby in persistent occipitoposterior presentation delivered with the aid of low forceps He was bottle fed of which he was weaned at eight months His weight at 1 year was 24 pounds (11 Kg) and at birth was 7 pounds 10 ounces (3.5 Kg) He was fed orange juice after he was 4 weeks of age and every effort of giving him cod liver oil or viosterol would upset him The bowel movements would become loose and green with some mucus and a very foul odor Often they would be constipated Stool examinations were negative for blood or worms He has been getting ultraviolet and natural sunlight treatment, but still shows very slight traces of rickets At 6 months cereals were introduced and later eggs vegetables fruits and meats His stool has not been normal for months but in the last four weeks he has shown definite anorexia belches often does not vomit and suffers from constipation The stool is especially foul and at times is black it is well formed and often consists of fecal masses the size of hazelnuts I have stopped the eggs and meats completely, have limited vegetables to potatoes and have prescribed milk cereals and bread and have found him showing definite improvement However after two weeks, when the eggs and the meats were reintroduced the old condition returned The child otherwise is mentally and physically well and has not had any other illness I will appreciate your advice in this stubborn and discouraging case of chronic digestive disturbance. I would add that several good pediatricians have seen the patient with me. Their advice did not materially alter the treatment and all expressed the opinion that the child would outgrow the condition. Please omit name.

M D, New York

ANSWER.—Constipation is noted as the chief disturbing factor in this case. Certain dietary changes may aid in overcoming the difficulty If the foods are still being finely strained, it might be advisable to resort to a coarser diet. If the quantity of milk in the diet is excessive, the amount should be reduced, and pulpy fruits and more bulky vegetables should be given The addition of carbohydrates in the form of molasses, honey and jelly will increase fermentation and aid peristalsis Coarser cereals, bran and whole wheat bread are advised Plenty of water should be offered between meals Agar-agar, an indigestible carbohydrate obtained from seaweed, has the ability to absorb large amounts of water and forms a bulky mass in the intestinal tract, thus stimulating peristaltic movements Cathartics are habit forming and contraindicated At 22 months the child should be trained in regular habits of evacuation With proper instruction he should be taught the habit of going to stool and the correct muscular coordination for proper evacuation. If a proper dietary regimen and adequate habit training do not alleviate the constipation, obstructive causes should be sought for and eliminated

RELATION OF HEART LESION TO TONSILLECTOMY

To the Editor—I recently saw a 9 year old girl with a mitral valve lesion due to rheumatic fever and a septicemia The father of the girl said that doctors had attributed her valve lesion to having a tonsillectomy at 4 years of age. I know that one does not take tonsils out before the age of 6 usually but is there any evidence that tonsillectomy alone will cause a heart lesion? I have a boy at present 5 years of age who cannot eat solid foods and can hardly breathe. I intended to take his tonsils out next month but the boy's father overheard our conversation Would you kindly give me the indications for tonsillectomy in youngsters under 6? Please do not publish my name

M D., Michigan

ANSWER.—Tonsillar infections may and perhaps often do cause infections of other parts of the body, such as the joints and the endocardium, but it is inconceivable how the removal of tonsils as such could cause a heart lesion Perhaps in many instances involvement of the heart and other structures is present in cases of chronic tonsillitis, but attention is called to the lesion after the tonsils have been removed, and then erroneously the condition found may be ascribed to tonsillectomy though the operation itself was not the cause There are no definite age limits at which tonsillectomy may be done. It is a question of clinical history which is the deciding factor If there is sufficient evidence of infection in the tonsils causing injury to the patient the tonsils may be removed when the child is even only 12, 15 or 18 months of age. On the other hand, indications for tonsillectomy are usually present in the majority of cases during the ages of 3 to 8 or 10 years, but no definite time limit can be set, and indication for operation is governed by the signs and symptoms in each individual instance. There are many indications for tonsillectomy, such as repeated attacks of tonsillitis, particularly with the attacks becoming more frequent or more severe as time goes on such marked hypertrophy as to interfere seriously with breathing or swallowing, definite and repeated involvement of the regional cervical lymph glands with acute exacerbations, definite signs of focal infection in the kidneys, heart and so on coincident with or following the attacks of acute tonsillitis, tumors of the tonsils, interference with proper speech by large tonsils, or a long standing reflex cough

due to submerged tonsils in which all other possible causes for a cough have been eliminated. The presence of caseous plugs in the crypts causing fetor ex ore or giving rise to a bad taste serves as an indication for tonsillectomy.

USE OF CORBUS-FERRY FILTRATE IN GONORRHEA

To the Editor—Two years ago a married man aged 31 came to me with an acute gonorrheal urethritis. The infection remained in the anterior urethra throughout the treatment which consisted of the usual instillations of mild antiseptic solutions and some of the commonly used urinary antiseptics by mouth. After about eight weeks the infection cleared up completely as evidenced by negative smears after prostatic massage and the introduction of sounds. In December 1935 the patient again appeared with an anterior urethritis which on examination and smear proved to be a recent gonorrheal infection. Having read the very favorable literature regarding the latest treatment of gonorrhea with gonococcus filtrate I persuaded the patient to have me use this new method in the treatment of his infection this time. On about the fifth day of the appearance of the discharge I gave him the first injection of gonococcus filtrate 0.05 cc intradermally. There was a skin reaction about 1½ inches in diameter. A few days after the injection a positive urethritis also was present. December 31 he received a second injection 0.075 cc. with a reaction 2 inches in diameter. Jan. 7, 1936 he received a third injection of 0.1 cc. with a 3 inch reaction. During this time I had also been using the mild instillations just as I had the first time he had gonorrhea. January 12 he became ill with a temperature of 101 and was ordered to bed. The next day an acute prostatitis was discovered. January 18 while still in bed he developed an acute epididymitis of the left testicle. Conservative treatment was used and he went to work January 27 feeling much better although the left testicle was still swollen. From then on the urine started clearing and the discharge diminished. February 5 a fourth injection of gonococcus filtrate was given (only 0.05 cc.) with a resultant reaction 3 inches in diameter. Today he appeared in my office with an acute epididymitis of the right testicle. He feels strongly (as do I reluctantly) that the gonococcus filtrate has given him all this trouble at this infectious period. I wonder if there have been others who have had the same experience. I know that I have followed the technique carefully. I am going to be more watchful henceforth of the adage. Be not the first by whom the new is tried nor yet the last to lay the old aside in medical practice. But this has been a rather sad experience for both my patient and myself. If this should be printed please omit my name.

M D Illinois

ANSWER—Despite the enthusiastic reports of a few urologists and the impossible claims of the manufacturer's representatives, the experiences of this patient are not unique. The most striking published report of grief from the use of Corbus-Ferry gonococcus filtrate is to be found in an article by Dr. H. M. Spence in the *Oklahoma State Medical Association Journal* (28:442 [Dec.] 1935) abstr. *THE JOURNAL* February 8, p. 498. A recent survey of a number of urologists regarding their opinions of it based on actual trial showed that, with but few exceptions, its use had been discontinued either because of lack of therapeutic results or the too common precipitation of serious complications following its administration.

TREATMENT OF PINWORM INFESTATION

To the Editor—I have been consulted by a woman aged 29 who has been infested with pinworms (*Oxyuris vermicularis*) for the last four years. During this time she has taken treatment for the condition more or less constantly and has been prescribed for by at least half a dozen physicians. A careful check up on prescriptions given her show that she has taken every vermifuge recommended for the condition at least once but even so she continues to pass one or two worms at a time at frequent intervals. The diagnosis has been confirmed by microscopic examination which shows typical male and female worms and ova. Proctoscopic examination is essentially negative. Vaginal examination is negative. The patient has been told about the usual method of reinfection and has almost developed a phobia for the condition and washes her hands continually in bichloride solution. No other member of the family shows any evidence of infestation. During the past four years the patient has lived in three states and numerous communities which I believe proves that she is carrying her own source of reinfection. Any further suggestions as to treatment will be appreciated. Please omit name.

M D Kansas

ANSWER—The relative futility of "washing hands continually in mercury bichloride solution" and the proper hygiene for such cases is so well brought out in Harry Beckman's *Treatment in General Practice* (Philadelphia: W. B. Saunders Company, 1934) that one can do no better than to quote verbatim:

The length of the life cycle of *Oxyuris* from the time the eggs are ingested to the time the females crawl out of the anal opening is a little more than two weeks. It therefore the conveyance of eggs from anus to mouth by contaminated fingers can be absolutely prevented for a period of two to three weeks the infestation will be cured. This apparently simple feat is extremely difficult to accomplish. The treatment should begin with a full bath with soap and water. Special attention being paid to the anal region. After this the anal region and perineum are to be anointed with an ointment composed of 2 per

cent of ammoniated mercury in equal parts of lanolin and petrolatum, a pad of cotton applied, and the child clothed in heavy drawers that are closed front and back. After each defecation the anal region is to be thoroughly washed with soap and water, the ointment and a fresh pad applied, and the drawers put on again. At night, when the itching is at its worst, the following anesthetic preparation may be substituted for the mercury ointment:

| | Gm or Cc | |
|-------------------------------------|----------|---------|
| R. Ethyl aminobenzoate (benzocaine) | 3.0 | gr. xlv |
| Salicylic acid | 0.75 | gr. xij |
| Hydrous wool fat (lanolin) | 15.0 | ℥ss |
| Petrolatum to make | 30.0 | ℥i |
| Label: Apply as directed | | |

"It may be necessary to tie the hands, especially at night, so that they cannot be carried to the site of itching. In any case, the cleansing of the hands is of the utmost importance since ordinary washing will not suffice to rid them of the eggs. They must be thoroughly and frequently scrubbed with brush, soap and water, and the nails kept scrupulously clean. Daily full baths are desirable. If several children are closely associated, all must be simultaneously treated else mutual reinfection will be certain to take place. Bed sheets should be boiled at least twice weekly."

Internal and rectal treatments are secondary in importance to this regimen.

ANEMIA IN BLOOD DONORS

To the Editor—I have under my care a white man aged 26 weighing 150 pounds (68 Kg.) giving a history suggestive of gastric ulcer. The history reveals the astonishing information that the patient has served as a blood donor in one of our larger university hospitals for the past thirteen months. During this period he has given blood for twenty-two transfusions averaging 250 cc. to a transfusion. 1. What is the total volume of blood normally present in a 150 pound white man? 2. What is the weight of the blood in such a person? 3. What is the possible etiologic factor in the gastric ulcer? 4. What possible damage might result from repeatedly acting as a donor in so short a time? Please omit name.

M D New York

ANSWER—1. According to the usual methods of calculation, the total volume of blood in a healthy man weighing 150 pounds (roughly 70 Kg.), would be from 3,500 to 5,400 cc. There is reason to believe that the blood volume would probably remain fairly constant after repeated bleeding of say 250 cc. at intervals of about two weeks.

2. The weight of the blood in such a person according to current concepts would be from 3.5 to 4.9 Kg., which would be the equivalent of from 3,500 to 4,900 cc. in volume as the average specific gravity of human blood is about 1.055.

3. On general principles it cannot be questioned that the debility following loss of blood may favor the development as well as the recurrence of gastric and other ulcers.

4. Experience indicates that there would be danger of grave secondary anemia from the loss of 250 cc of blood about every two weeks for a period of thirteen months.

ERYSIPELOID

To the Editor—I am a physician for a rendering plant where dead horses, cows and other animals are handled. Employees have an inflammatory condition usually of the hands and I am at a loss to make a proper diagnosis. The condition comes about often by the entrance of some organism through the slightest scratch of the skin. It appears somewhat like erysipelas and seldom suppurates. It generally runs a course of about three weeks. I hope that you will be able to suggest the various possibilities as to the etiologic organisms. Please do not mention my name in publication.

M D Michigan

ANSWER—The skin disease described is undoubtedly erysipelas which is caused by *Bacillus erysipellatus suis* the same that is responsible for swine erysipelas "diamond skin disease." The organism is widely disseminated in nature as a saprophyte and pathogen. It is estimated that 50 per cent of healthy swine are carriers of this infection and it is frequently found in dead animal or vegetable matter. Its virulence and its morphology are changed by passage through animals.

The disease in man, who is relatively immune is usually mild as described in the query. Sharply circumscribed round or polycyclic red or bluish patches appear on the fingers at the site of some small wound and slowly spread seldom going beyond the wrist. After a few weeks it subsides the color changes to yellowish and the lesions disappear usually without scaling. There are as a rule no subjective symptoms, but deep pain, burning or itching may be felt.

The disease as it is seen among fishermen infected from the slime about the fish may be more severe with swelling of the part lymphangitis, swollen and tender lymph glands and even at times mild constitutional symptoms.

Rarely the acute septicemic form occurs, with diffuse erythema and severe illness, even fatal in rare instances. A chronic form with arthritis and a peculiar vegetative endocarditis also occur. These are reported from Germany but are almost unknown in this country. Not only are fishermen, handlers of swine and pork, cannerymen of fish, veterinarians, and those who handle dead animals infected, but accidental cases occur from handling rabbits, dead or alive, from the sting of a jelly fish, and even from wounds from the spines of dried fish.

A vaccine killed at 70 C causes in healthy rabbits, according to W. Jadassohn (*Handbuch der Haut und Geschlechts Krankheiten* 2:412) only a slight reaction. In rabbits that had recovered from erysipelas, a marked reaction was the response.

The treatment includes rest and the application of heat and ultraviolet rays. Most efficacious is the serum of animals immunized to swine erysipelas. This often causes serum sickness. It has been found, however, that small doses, 5 cc. injected subcutaneously in many points about the lesions, will cause a prompt regression. Occasionally it is necessary to repeat the injections after a few days. See Klauder, J. V., and Harkins, M. J. *Erysipelas in the United States*, *THE JOURNAL*, April 11, 1931, page 1205. Direct communication with Dr. Klauder, 1934 Spruce Street, Philadelphia, is suggested.

UNDULANT FEVER

To the Editor—I have a boy aged 12 in my practice with undulant fever. He has probably had it about two months. He is not nor has he been acutely ill but his temperature has been 100 F or a little over every night for at least six weeks. His physical examination is entirely negative. He feels fairly well in the morning but in the afternoon when his temperature goes up he is listless and weak. His blood serum agglutinates *Brucella abortus* in a dilution of 1:10,000. The white blood count is 6,400 with 81 per cent small lymphocytes. Are any of the various serums or vaccines that have been recommended worth using in such a case as this? Please omit name.

M D, Massachusetts

ANSWER—*Brucella melitensis* (abortus) vaccine (N N R) appears to exert a favorable influence on cases of brucellosis (undulant fever) of the type described. The vaccine is available through the usual trade sources. In view of the age of the patient it would seem advisable to begin the treatment with smaller doses than the 0.25 cc. doses ordinarily recommended. The dosage of the vaccine should be gradually increased, at intervals of three days, to approximately 1 cc. As the dosage is increased, a febrile reaction ordinarily occurs. The injection of a like amount of the vaccine three days later will ordinarily not produce so marked a reaction. If a second marked febrile reaction should occur, the dosage should be reduced to half of the amount that produced the reactions for at least two injections, after which the dosage may usually be increased without the development of severe reactions. Following the development of a systemic febrile reaction the fever usually exhibits a declining trend. The response to vaccine therapy has been best in those patients who have experienced one or two systemic reactions. The average course of vaccine therapy requires approximately 10 cc. of the vaccine. Dr. Lee Foshay of the department of bacteriology, University of Cincinnati has developed an antiabortus serum that is apparently effective during the first three months of the disease. I. F. Huddleson of Michigan State College East Lansing, Mich., has utilized a broth filtrate of *Brucella* organisms known as "brucellin," in the therapy of brucellosis with apparently good results.

SUBINVOLUTION OF UTERUS NOT RELATED TO MONSTROSITIES

To the Editor—I have a woman patient who previous to her last pregnancy had a subinvolved uterus. She recently delivered at term a monster which died after delivery. I am anxious that complete involution should take place this time. Would you advise me as to the treatment of choice in such cases of subinvolution of the uterus? Please omit name and address.

M D Oklahoma.

ANSWER—There is no positive evidence that subinvolution is one of the causes for monstrosities. These are usually due to some defect in the germ plasma. Certain kinds of monstrosities and possibly some defects of germ plasma are due to diseases of the uterus particularly endometritis—the real endometritis not the hypertrophy that has recently been found to result from abnormal hypophyseal action. It is probable also that subinvolution which was formerly ascribed to infection and laceration of the cervix may also be due to abnormal functioning of the pituitary gland. Ergot preparations, hot douches, diathermy and other heat application methods, uterine massage and active outdoor exercise have all been employed in the treatment of subinvolution. No one has yet tried endocrine therapy and a few experiments in this direction might add to our knowledge.

CARCINOMA OF OVARY

To the Editor—1 What is the frequency of carcinoma of the ovary in females prior to the establishment of the menstrual cycle (age 13 years)? 2 What is the frequency of the usual type of malignant tumor of the ovary in the same case as 1? 3 What is the prognosis as to removal of an unruptured ovary? 4 As to removal of a ruptured ovary? May I have an early reply? Kindly omit name.

M D, Massachusetts

ANSWER—1 and 2 In a collection of 1,764 cases of tumors of the ovary, Olshausen found sixty-one cases below the age of 10 years. Hubert in 1901 reported 175 cases of tumors of the ovary up to the age of 17 years. He found 115 benign and sixty malignant tumors. Of the malignant tumors, twenty-eight were carcinoma (solid and cystic) and thirty-two sarcoma. Other statistics of 202 cystic tumors of the ovary in children showed 35 per cent cystomas, 31 per cent dermoids and 34 per cent malignant tumors. Sarcomas are more common in children than carcinomas.

3 and 4 The prognosis of ovariectomy depends entirely on the degree of malignancy of the tumor. The operation itself has a very low risk. Doederlein reports a mortality of 13 per cent in 452 operations for benign lesions and a mortality of 15 per cent in seventy ovariectomies because of carcinoma or sarcoma. Segalowitz found a mortality of 53 per cent in a collection of 1,134 ovariectomies for benign lesions and a mortality of 179 per cent in 356 malignant conditions. Rupture of a cystic ovary (spontaneous or during operation) does not influence the prognosis of benign cysts. In malignant lesions the consequent spreading of malignant material through the peritoneal cavity makes the prognosis very much worse.

BLOOD TRANSFUSION FROM SYPHILITIC PATIENT

To the Editor—Would you please let me know whether a blood transfusion can be given by a donor who has had secondary syphilis, who has had adequate treatment on modern lines and whose blood and spinal Wassermann reactions are persistently negative? Please omit name.

M D, Massachusetts

ANSWER—Under ordinary conditions one would not accept such an individual as a blood donor. All prospective donors should be questioned as to whether they have ever had syphilis, malaria and other infectious diseases regardless of negative tests at the time.

Under unusual conditions, such as an emergency or when there is an unusual blood group in which a delay necessary to obtain another donor might result in serious complications or death to a patient, one would advise the use of such a donor.

It is probable that any danger to the patient would be slight compared to the deprivation of blood, and there certainly would be much less risk than is entailed in many surgical and even medical methods of treatment.

DANGERS OF INFECTION FROM EMBALMED BODIES

To the Editor—To what extent are the present methods of embalming an absolute safeguard against the spread of disease? Are there any disease conditions wherein for contagious reasons it would be inadvisable to reopen the casket at the church or the grave for the benefit of relatives and friends? If you reply through *THE JOURNAL* please omit name.

M D Missouri

ANSWER—Undoubtedly thorough cleansing of the body externally, including its surroundings, and injection of the vascular system with embalming fluid containing an adequate amount of formaldehyde will disinfect the body sufficiently to prevent the spread of infectious materials. In general, health departments, however, in order to secure the maximum safety after taking into consideration all the circumstances surrounding deaths from acute infections, have adopted rules that do not permit public funerals in deaths from certain acute infectious diseases.

TRANSMISSION OF TAPEWORM FROM DOG

To the Editor—I have a small dog which occasionally becomes infested with tapeworm. He is often fed bits from the table at meal time. Will you kindly inform me whether there is danger of transmission of the canine variety of tapeworm to man and whether man is susceptible?

REGINALD K. FRANCIS M D Inglewood Calif

ANSWER—As the dog harbors a number of tapeworms of different genera some of which can live in man as adults (intestinal infections) or as larvae (somatic infections) it is impossible to answer the question without knowing the species of worm involved. It is probable that the tapeworm referred to is *Dipylidium caninum* in which the larvae develop in the dog louse or flea and in which human infestations are acquired by the accidental swallowing of these insects. Less than a hundred such infestations of man are known and they are exceedingly rare in the United States.

Book Notices

The Adrenals By Arthur Grollman Ph D M D Associate Professor of Pharmacology and Experimental Therapeutics in the Medical School of The Johns Hopkins University Cloth. Price \$5 Pp 410 with 17 illustrations. Baltimore Williams & Wilkins Company 1936

This is chiefly a compilation, with little if any critical analysis, of literature covering some prominent phases of the subject. A bibliography of 704 references is appended. In view of the fact that this corresponds to not more than about a tenth of the total number of published articles on the adrenals (as a conservative estimate), the author may be congratulated for his courage in undertaking to sift out of so enormous a mass of heterogeneous material that which he considers worthy of record. In view of the superabundance of available literature, an onus probandi rests on the author of a monograph to establish its *raison d'être*. Its merit may be judged by its content of new or unpublished material, critical analysis of existing literature, especially controversial subjects, elaboration and discussion of the author's own original contributions and of his experience in the field, and other similar considerations. These form the basis of the present review.

Half of the space in the book is devoted to historical, anatomical and clinical material. In addition, some forty-two pages are devoted to chemistry and pharmacology of epinephrine. This seems entirely out of proportion to the space devoted to the physiology and pathology of an organ whose obscure function in health and disease has been a challenge to investigators for nearly a century. At any rate, the subjects are sufficiently and more extensively treated in existing available works.

The outstanding new contribution is represented by the coinage of the term "androgenic" to designate a zone in the adrenal cortex already well named as the "juxtamedullary" zone. The latter indicates its anatomic position while the former implies a functional distinction that is far from being established. According to information obtained from the Council on Pharmacy and Chemistry the term androgenic has been employed previously, by others, to designate activity of substances, termed "androgens," that are extracted from testes and from urine. Although pathologic manifestations involving secondary sex characters are known in which neoplastic development in the adrenal may be found in this zone, it appears unwarranted to designate specifically this portion of the adrenal by a term which has sex functional implications, unless such function is adequately proved. The author leans strongly for support on this pathologic evidence but overlooks the significance of the fact that the juxtamedullary zone undergoes or has undergone regression at the period when secondary sex characters are manifested, the very period when one should expect continued presence or hyperplasia of cells that are endowed with androgenic potentiality.

A number of inaccuracies occur, e g (p 88), referring to the intestinal strip as a reagent for detecting epinephrine, it is stated that "Cannon and Hoskins claim this test to be sensitive to epinephrine in a dilution of 1 to 400 millions." This cannot be found in the paper by Cannon and Hoskins referred to, although in a previous paper by Cannon and de la Paz there is evidence that their intestinal strips reacted to epinephrine concentrations of from 1 to 1 million to 1 to 3 million, while Magnus obtained reactions with 1 to 20 million. Another, more glaring inaccuracy is the statement (p 98) "Stewart and Rogoff's failure to demonstrate that sensory stimulation does not increase the secretion of epinephrine was due probably to the experimental methods which these authors utilized." Such a statement is absurd, since the literature clearly shows that Stewart and Rogoff have consistently found the exact opposite of what is here alleged from their experiments. Indeed, this is one of the principal points of difference between them and Cannon, in their long standing controversy.

Regarding this controversy, which has held the interest of physiologists for many years, the author has almost nothing to say. Cannon's theory of emergency function of the adrenals is scarcely given mention, although this is not only the most prominent but the most seriously contested theory of adrenal function. During many years Cannon and his pupils have ably and intensively labored to support the theory while, with equal ability and intensity, Stewart and Rogoff have elaborated experimental evidence controverting it. This important phase of the subject relating to adrenal function is evaded by assuming the safe position that Cannon may be both right and wrong, with the statement (p 110) "Cannon and his collaborators are probably correct in assuming an increased output of epinephrine under various conditions in which epinephrine by its pharmacodynamic reactions would be useful to the organism in an emergency. It is very doubtful, however, if the amounts of epinephrine secreted under these conditions would suffice to be of any significance to the organism as demanded by Cannon's theory." The supposed relation of "sympathin" to various reactions attributable to epinephrine and also its relation to the emergency theory is apparently not considered. The author appears satisfied that "different methods" can account for wide differences in a "normal" rate of secretion, although the figure for the normal rate alleged by one author is about 100 times that of the figure given by another. The significance of such improbable functional variations and of the relation of these quantitative discrepancies in a normal phenomenon to functional concepts is not adequately considered.

The chapter on the adrenal cortex is not less incomplete than that on the medulla. Without depreciating the value of the author's own contributions in this field, it may be said that, since his work is too recent (since 1933) to have the advantage of confirmation, undue emphasis and disproportionate space have been given to it. Premature credence is given also to some physiologic, chemical and clinical concepts that are by no means adequately established. The original work of Rogoff and Stewart on the adrenal cortex and their demonstration of the possibility of obtaining active cortical extracts is not mentioned, and while oral administration of active cortical material is recommended in the treatment of Addison's disease, it apparently relates to the unproved 'charcoal' product described by the author and not to the product of proved merit reported by Rogoff in a relatively large, controlled series of cases of Addison's disease. The section devoted to clinical considerations is much too brief to be very useful. In spite of fairly good compilation of general conclusions existing in papers representing a prominent portion of the literature on the subject, it seems that the publishers are hardly justified in representing the book as "a complete monograph on the adrenals."

Traité d'embryologie des vertébrés Par A Brachet professeur à l'Université de Bruxelles. Revue et complétée par A Dalcq et P Gérard professeurs à l'Université de Bruxelles. Second édition. Cloth. Price 130 francs. Pp 690 with 603 illustrations. Paris Masson & Cie 1935

Brachet's book on the embryology of vertebrates was published in 1921. It was a welcome contribution to the science of anatomy. Agassiz proclaimed long ago that many of the most significant and illuminating facts of comparative anatomy must lie in comparative embryology. They throw light on the course of evolution, the principles of structure and the nature of organs. Brachet's work was characterized by method, logic and clarity of statement. His book was not simply a storehouse of facts, it was a clear logical, thought provoking interpretation of them. His mental qualities together with his winning personality won for Brachet world wide respect and popularity among anatomists and zoologists and his book was welcomed. It was devoted purely to general morphogenesis in contrast with most books in the field which, written by anatomists, made embryology ancillary to organogenesis or histogenesis. In 1930 Brachet began work on a second edition but shortly afterward was stricken by his final illness. The work was then taken over by his colleagues in the University of Brussels, Professors Dalcq and Gerard. They revised and completed it along the lines projected by the author. The first part 356 pages, deals with general embryology—sex cells, blastulation, gastrulation and germ layers. The second part, 317 pages deals with the embryology of special regions and organs. New facts requiring modification of the older inter-

pretations have necessitated the rewriting of the chapters on gastrulation, formation of the embryo, and origin of gonocytes. Professors Dalcq and Gerard have done their work well. The new edition like the old, excels in the logic and clarity of its presentation and interpretation. Many new illustrations in black and white have been added, drawn mainly by the same artist, Van Wetter. The form and printing are in the excellent style characteristic of the publisher.

Allergy of the Nose and Paranasal Sinuses. A Monograph on the Subject of Allergy as Related to Otolaryngology. By French K. Hansel, M.D., M.S., Assistant Professor of Clinical Otolaryngology, Washington University School of Medicine. Cloth. Price \$10. Pp. 820, with 61 illustrations. St. Louis: C. V. Mosby Company, 1936.

Hansel's monograph is written not for the general practitioner but for the specialist in otolaryngology or allergy who is interested in the details of these related fields. It does not limit itself to allergy of the nose and paranasal sinuses. Bronchial asthma, gastro-intestinal allergy and migraine are as thoroughly treated. The one field covered too briefly is that of the dermatologic conditions. The literature is almost completely reviewed without editorial comment except at the end of certain chapters when the data are either conflicting or confusing. In such cases the author summarizes the data critically under the term "discussion." The first four chapters are devoted to such fundamental discussion as the physiology of the nose and paranasal sinuses, the biochemistry of the secretion, and the bacteriology of the nose and paranasal sinuses. An equally adequate treatment is then given to allergy in general. The rest of the book is devoted to clinical considerations of interest to the allergist and otolaryngologist. The chapter on roentgen examination of the paranasal sinuses is particularly well illustrated, with emphasis on the value of radiopaque substances. The treatment of hay fever is thoroughly considered in the last hundred pages. Hansel is to be congratulated on accomplishing more than the title implies. His book is the most authoritative and comprehensive one on the subject. In a field where the allergist should be a rhinologist and the rhinologist an allergist, he has covered the subject so thoroughly that it may well be a bridge of understanding between the two specialties.

Sammlung psychiatrischer und neurologischer Einzeldarstellungen. Herausgegeben von Prof. Dr. A. Bostroem und Prof. Dr. J. Lange. Band IX: Wach und Wahrträumen bei Gesunden und Kranken. Von Prof. Dr. F. Kehler, Direktor der Psychiatrischen und Nervenkl. der Universität Münster in Westfalen. Paper. Price 4.80 marks. Pp. 72, with 1 illustration. Leipzig: Georg Thieme, 1935.

This monograph deals with dreamlike experiences that occur in an altered state of consciousness, but in the waking state, and also with prophetic dreams or dreams of second sight. For the former common usage would permit the term "day dream," but the author specifically objects to this term as the dreamlike experiences dealt with are independent of time of day or night and must be distinguished from dreams by the fact that actually the subject is in the waking state despite changes in consciousness in muscular tension and in reduction of responsiveness to sensory stimuli approaching that found during sleep. The author describes various states of abstraction or preoccupation, such as the hypnotic trance, fascination and ecstatic states and distinguishes these from the day dream or waking dream. The waking dream is to be distinguished from the dream of the sleeping state among other considerations by the fact that the latter are not susceptible to the will of the dreamer, while the former to an appreciable degree may be induced or dissipated at will by the subject.

The waking dream is not characterized by the dissociation and incoherence that characterizes the sleeping dream. The waking dreams are pictorial. They are pseudohallucinatory in character—the subject is always correctly oriented as to their unreality. The content of the waking dreams may represent any of the conceptions or ideas of the waking or sleeping state. The dreams are emotionally positively and agreeably charged and gratify definite urges or impulses. They may be characterized as psychic devices for self gratification through phantasy images. With some individuals the content of the dream is sexual and the excitation and gratification sexual in character. The dream may be fairy tale like in character or may at times pertain to actual past experiences of the subject.

The author also discusses "wahrträume," or "true" dreams that is, the occurrence in a dreamlike state of a historical event of which the subject has no adequate knowledge, or of an event that occurs at the same or at a future time. He describes prophetic dreams and "second sight." The close relation of these to the waking dream is traced. The author feels that no scientifically adequate researches covering these phenomena have been as yet reported. He discusses its occurrence among normal and psychopathic subjects. The occurrence of the waking dream is dependent on instinctual drives or impulses, deriving its energy from forces dependent on the peculiar personality of the subject. Waking dreams are a peculiar development of the child's impulse to play. The author believes that this phenomenon can be included with other "instinct anomalies" and may be regarded in the same light as the well known deviations in the instinctual life, such as sexual perversions, opium and other drug addictions, and criminal instinctual acts. He reports a case from his own experience in which, over a period of years, the patient compulsively indulged in primarily wishful phantasy, to the exclusion of actual accomplishment. The author insists that he is dealing with a case that belongs to a distinctive psychopathic type, belonging to the group "constitutionally psychopathic" individuals. He emphasizes hereditary determination in his own case and summarizes the peculiarities as weakness of sense of reality, feelings of inferiority, incapacity for self determination, weak gregarious tendencies, weak sexual impulses, emphasized phantasy, poor capacity for concentration, and generally weak will. He emphasizes the passivity evidenced by his patient and other members of the family.

Descriptively, the author's treatment of his subject and material is splendid, and quite complete. From a dynamic psychologic point of view his discussion is suggestive but incomplete. If he is correct in relating the cases evidencing the phenomenon he discusses to other forms of addiction, it is likely that the particular passive need for and the neurotic utility of indulgence in the phantasy could be more sharply defined through psychoanalytic studies. The author is well aware of the compensatory and wishful character of the waking dreams in his cases, but how and why the subjects have been driven into the given patterns described is not stated and probably could not be adequately stated without psychoanalytic study. It is doubtful that the designation of a distinctive psychopathic type is warranted, since probably all gradations of the phenomena described can be observed with widely varying degrees of constitutional deviation.

The Postgraduate Instruction of Health Officers and Nurses with an Appendix Giving Suggestions for the Preparation of Sanitation Personnel. By Henry E. Meleney, M.D., Associate Professor of Preventive Medicine and Public Health, Vanderbilt University School of Medicine, and Walter S. Leathers, M.D., Professor of Preventive Medicine and Public Health and Dean, Vanderbilt University School of Medicine. Paper. Pp. 73. New York: Commonwealth Fund, 1936.

This monograph is a description of the cooperative project in postgraduate instruction of health officers and nurses that is being carried out by Vanderbilt University, the state health department of Tennessee and the county health departments of Rutherford, Williamson, Gibson, Sullivan and Davidson all in Tennessee. It is a recognition of the fact that public health work depends in the last analysis not on organization but on the qualifications of personnel. "It is obvious," say the authors, "that any physician who is placed in charge of a full-time health department at the present time should have had some kind of preliminary instruction in public health administration." The same is true, of course, of nurses. The prospective and indeed imminent expansion of state and local public health work as a result of federal aid through the Social Security Act has already created a large demand for qualified workers in public health. The only way in which new positions in the public health field can now be filled with qualified personnel is by robbing some other organization. It is one of the paradoxes of this depression that in the midst of widespread unemployment there is a serious lack of qualified personnel for desirable jobs waiting to be filled. Moreover there is certainly no excess of available educational facilities in this country for the training of public health personnel. The schools of public health that are organized for postgraduate training of physicians and nurses who seek to qualify

for public health positions are strained to the limit of their resources. Standards set by committees of state and territorial health officers advising the United States Public Health Service and the United States Children's Bureau have been established on a plane lower than was admittedly desirable, because the committees were forced to recognize the dearth of qualified personnel and the lack of adequate accommodations for large numbers of trainees. In the light of these circumstances, the experiment in Tennessee on the eminently practical basis that has been established should be watched with interest. Perhaps the most constructive benefit that might arise out of federal aid to local and state-wide public health work will be the better training of personnel. Whatever may be the ultimate fate of federal subsidies, public health organizations and the public whom they serve will derive a lasting benefit from improvement in the training and qualifications of public health workers.

A Classification for Medical Libraries with Introduction Local List Index of Parasites and General Index. By Cyril C. Barnard B.A. Univ. Dipl. in Librarianship F.L.A. Librarian London School of Hygiene and Tropical Medicine. Being a Thesis Approved for the Diploma with Honours of the Library Association (1931). Cloth Price 10s 6d Pp 142 London Percy Lund Humphries & Co Ltd, 1936

This adds another to the several classification schemes now available for medical literature. The author states that it was submitted to the Library Association (British) and approved for the diploma with honors in 1931. For financial reasons it was not published until this year. Now it is printed in type-writer type by means of the replica process, a method of printing known in this country as the planograph process. This work represents the result of twenty-one years of practical experience by the author in four medical libraries of widely different types. The principle underlying this scheme is that of specific entry, namely, one place for each topic, under which are grouped all its aspects. This, of course, is contrary to the principle adopted by the Dewey system, in which works on the anatomy, physiology, pathology and surgery of an organ are distributed in four different places. The system of notation adopted is the same as that used by Cutter, pure alphabetical notation with the exception of the local or geographic list, which is numerical. The author freely admits that considerable help was derived in developing his final scheme from the Boston Medical Library classification, which did not come to his notice until 1927, several years after his initial plan. The chief advantages claimed for his classification over the Boston scheme are (1) the greater power of expansion from the use of Cutter's notation, which makes it easier to insert new topics at the most appropriate place, and (2) the more logical basis for the arrangement of specific infectious diseases. Perhaps the greatest advantage of all in this new classification system is its excellent index, a feature which all other special medical classifications have neglected to provide.

Bewildered Patient. By Marlan S. Newcomer M.D. Cloth Price \$1.75 Pp 325 Boston Hale Cushman & Flint 1936

There is a great deal of useful information in this book, and in general the patient might be expected to benefit from its reading. The book is well written. There are certain errors which ought not to have crept in, as, for example, the author's endorsement of the idea that taking of sugar in an emergency gives an immediate increase of available energy in the presence of serious fatigue. There is a reference to milk as a perfect food, which also should have been qualified. The discussion of vitamin A and its relation to resistance is subject to interpretation favorable to certain commercial claims for vitamin A which have not been acceptable to the Council on Pharmacy and Chemistry of the American Medical Association. Neither would the Council agree that it is desirable to increase the amount of vitamin D in many foods by treating them with ultraviolet rays. The Committee on the Costs of Medical Care is referred to as a Committee of the American Medical Association, the Metropolitan Life Insurance Company and other organizations! On the other hand the chapter on what a physician can do for his patient is excellent. The inaccuracies that have been mentioned are small and few in number and are the more unfortunate because they mar an excellent work which as a whole will serve to do much to clear up the confusion of the bewildered patient.

Painful and Dangerous Diseases of the Ear. A Text Book for Students and General Practitioners. By R. R. Woods M.B. F.R.C.S.I. Surgeon in charge of the Ear, Nose and Throat Department Sir Patrick Dun's Hospital Dublin. Cloth Price \$5.25 Pp 188 with 43 illustrations New York & London Oxford University Press 1936

The author states that what he believes is much needed is "detailed instruction concerning such painful or immediately dangerous conditions as occur in general practice, while leaving more specialized and less urgent matter if it is to be learned at all, to postgraduate study." This little work is systematically arranged. A chapter on essential anatomy of the various parts of the ear is followed by one on instruments, method of examination, syringing and cleaning of the ear which topics constitute the first part of the book. The author gives important points regarding the handling of appliances such as the aural speculum and the otoscope, in order that no pain or discomfort may be occasioned the patient. In the second part under the heading of acute uncomplicated aural inflammations the subjects of acute otitis externa and acute otitis media are discussed. Next come differential diagnosis of earache, acute otitis media in infants, and chronic suppurative otitis. The third part of the book is devoted to acute mastoiditis, and the fourth part to intracranial complications of ear infections. The book in a brief way gives definite information, which should be of special value to students and of more value to general practitioners and in some cases may even be used to advantage by those who are entering on the specialty of otology. The illustrations are clear and of a practical character.

Preventive Medicine and Hygiene. By Milton J. Rosenau Professor of Preventive Medicine and Hygiene Harvard Medical School. Sixth edition. Cloth Price \$10 Pp 1481 with 147 illustrations New York & London D. Appleton Century Company Inc 1935

This standard textbook on preventive medicine and hygiene, the first edition of which appeared in 1913, is distinguished in its latest edition, as always, by its completeness, its clear and useful descriptions of disease, and the technics of prevention. Numerous authorities have been consulted and have made contributions in special fields. The discussions of subjects that have come into prominence in preventive medicine and hygiene are particularly valuable. Notable are the sections on food poisonings, tularemia, air conditioning, radiation and mental hygiene. No health officer or public health department can function effectively without adequate information such as is contained in compact and convenient form in this book. A complete index adds greatly to the usefulness of the volume both for reference use and as a textbook. The bibliographies are extensive and cover source material in many languages. The book should have a place in the libraries of medical schools, health departments and other public health agencies, and in the library of the progressive physician. For the public library with limited funds this would make a comprehensive and useful reference work. The book contains relatively few illustrations, but these are well selected. There are many charts and useful statistical tables.

Thérapeutique hydro climatologique des maladies du foie et des voies biliaires. Par Paul Carnot professeur de clinique médicale à la Faculté de médecine de Paris Maurice Villaret professeur à la Faculté de médecine de Paris et René Caschera chef de clinique à la Faculté de médecine de Paris. Paper Price 20 francs Pp 152 with 4 illustrations Paris Masson & Cie 1935

This volume discusses briefly an ancient method for the treatment of the diseases of the liver and bile tracts and their associated gastro-intestinal complications by the use of various mineral waters. Empirically it has been known for centuries that these waters are of definite benefit in the treatment of chronic cholecystitis liver 'sclerosis', hepatic congestions and icterus. An attempt is made to summarize the clinical and experimental data collected over a long period. The analyses of the waters at the various French spas are given together with indications for their use in the various diseases. The more important places in France are listed and included is a brief description of the waters and a summary of the diseases for which they are apparently suited. A high degree of enthusiasm is expressed and probably should be taken with some reservation. The volume will be of some benefit to the physician in this country who is suggesting French spas for therapeutic reasons.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Privileged Communications Testimony of Physician in Absence of Jury.—During the trial of a personal injury action, a physician who had examined the plaintiff was permitted, on behalf of the defendant, to testify, in the absence of the jury, concerning the plaintiff's physical condition at the time of the examination. Later this same witness was permitted to answer hypothetical questions based on the previously given testimony. The admission of this testimony, said the Supreme Court of Mississippi, constituted error. Section 1536, Code of Mississippi, 1930, accords a privileged status to matters ascertained by a physician during the course of his examination of a patient. The fact that the disclosure in the present case was in the absence of the jury was considered immaterial. The policy of the privileged communications statute, said the Supreme Court, should be strictly observed. It is neither permissible to disclose such communications before a court in the absence of the jury, nor may hypothetical questions be asked a physician as an expert embracing matters testified to by him, without the consent of the patient. Although in the opinion of the court the testimony of the physician was inadmissible, the judgment of the trial court for the defendant was affirmed because it was the only one that could have been rendered on the facts in the case.—*Powell v Newman Lumber Co (Miss)* 165 So 299

Workmen's Compensation Acts Death in Relation to Trauma and Preexisting Leukemia.—Henry was employed at the defendants dairy farm. On July 10 and 11 he was treated for a condition on his right hip resembling a boil and for an encrusted lesion on his right ankle. At this time it was suspected that he had leukemia. On July 17, a calf kicked or stepped on his left ankle inflicting a scratch. The area surrounding the scratch became red and swollen. On July 31 he sustained a contusion of the chest and a general shaking up when a cow butted him. An ulcer developed on his left ankle which resulted in gangrene of his left leg, septicemia set in, and he died on August 12. The claimant, Henry's widow, applied for compensation under the workmen's compensation act. The commissioner found "The leukemic condition which [decedent] had was aggravated by the sepsis in his left ankle following the injury of July 17th and by the general shaking up and bruising of July 31st" and "although monocytic leukemia is in itself fatal, the decedent's death was hastened by the sepsis and by the shaking up and bruising which was followed by the septicemia." The commissioner concluded that the traumas were the immediate and proximate cause of Henry's death and awarded compensation for a period of 312 weeks. The superior court, on appeal, sustained the award in part but remanded the case for a finding as to the expectancy of life in monocytic leukemia so that an apportionment of compensation might be made under section 5223 of the workmen's compensation act which provides "In the case of aggravation of a pre-existing disease, compensation shall be allowed only for such proportion of the disability or death due to the aggravation of such pre-existing disease as may be reasonably attributed to the injury on which the claim is based. The claimant and the defendants thereupon appealed to the Supreme Court of Errors of Connecticut.

The defendants contended that even if injuries and septicemia had occurred which they denied Henry's death was caused solely by leukemia without aggravation by such injuries. The claimant however contended that the superior court had erroneously construed the commissioner's finding to mean that the cause of death was leukemia aggravated and accelerated by bodily injury rather than injury with leukemia merely a contributing cause. The Supreme Court of Errors held that the commissioner's finding should be interpreted as meaning that Henry was afflicted with a disease which would ultimately be fatal but that by reason of his injuries his death occurred

earlier than it would normally. The section pertaining to apportionment of compensation, said the court, applies whether the immediate cause of incapacity or death is the preexisting disease aggravated by injury, or whether the cause is the injury the incapacity from which has been increased by the preexisting disease or the death from which has been accelerated by it. However, the existence of a constitutional condition or latent tendency predisposing an employee to an injury does not subject him or his dependents to an apportionment unless there is a preexisting disease which, operating in conjunction with the injury, does in fact increase the incapacity or accelerate the death. Furthermore, in the opinion of the court, the evidence indicated that the maximum expectancy of life in monocytic leukemia was much less than the period covered by the award.

The Supreme Court of Errors could find no error in the judgment of the superior court and therefore affirmed it.—*Henry v Keegan (Conn)* 183, A 14

Workmen's Compensation Acts Rupture of Intestine Allegedly Due to Trauma.—The claimant, Pipkin, originally applied to the workmen's compensation commission for compensation for a hernia which he alleged resulted from accidental injuries sustained in the course of his employment. The deputy commissioner denied compensation because the claimant had failed to prove that the descent of the hernia had immediately followed the cause as was required by the workmen's compensation act. Subsequently, the claimant again applied to the commission for compensation, claiming that the accident to which he had previously attributed the hernia had caused a rupture of his small intestine. The commissioner awarded him compensation on this claim. This award was affirmed by the court of common pleas, whereupon the employer appealed to the supreme court of New Jersey.

The claimant testified that while lifting heavy barrels he felt a strain or "kink" in the region of his stomach and that later on in the same day a lighter barrel slipped from his grasp, struck him in the right abdominal region and caused him great pain in his groin. The claimant thereafter noticed a "big red mark" on his abdomen. He quit work and went home. That evening he entered a hospital, where, on the following morning, he underwent an operation for a rupture of the small intestine. The medical witness for the claimant testified that the rupture of the intestine was the result either "of a strangulation or a blow," and that "it could have been" the proximate result of the accident. The claimant must do more, said the court, than show that the condition "could have been" the result of the accident. While the claimant's evidence was meager and uncertain, leaving the matter in the realm of doubt and speculation, the testimony presented by the employer was definite and persuasive that the ruptured intestine was not caused by the accident. In the opinion of the supreme court the claimant was not entitled to compensation, and the judgment of the lower court awarding compensation was reversed.—*Wolfe & Co v Pipkin (N J)* 183 A 187

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Intra-gastric Photography.—Finkelstein has used intra-gastric photography in 216 patients, roentgenography and intra-gastric photography agreed in the examination of 153 patients. Of these, fifty were reported as normal, fifty-two suffered from carcinoma of the stomach and fifty-one showed the presence of gastric ulcer. In seven patients the roentgenologist suspected carcinoma. However, the intra-gastric pictures were definitely positive. Three of these patients were operated on and the diagnosis was confirmed. In the remainder of the series, both methods differed in their diagnostic pointings. In fifteen of these patients, the intra-gastric pictures showed the presence of ulcer, most of the ulcers being quite shallow. Thirteen of these patients were roentgenographed, with the diagnosis of pyloric carcinoma in two and with negative results in the remainder. Three of this series were operated on and the diagnoses by intra-gastric photography were confirmed. In the remaining ten patients, the diagnosis was substantiated by the history and subsequent clinical course. Chronic gastritis was diagnosed twenty-eight times. In twenty-seven instances the roentgen reports were negative. In one patient the report was carcinoma of the stomach. Operation proved the presence of marked hypertrophic gastritis with no evidence of carcinoma. Three cases of gastric carcinoma were diagnosed correctly by intra-gastric photography. This observation was proved by operation on two patients, the third died with evidence of carcinoma and metastases. In two of these subjects the roentgen diagnosis was gastric ulcer, in one 'no defect' was noted. On the other hand in eight patients the roentgen examination showed the presence of ulcer which was not the diagnosis after intra-gastric photography. One of these patients was operated on but no ulcer was found. In two patients who had been operated on previously for gastric ulcer and a gastro-enterostomy performed, the roentgenograms showed patent stomas. The intra-gastric films however failed to reveal the site of the gastro-enterostomy. Intra-gastric photography should prove useful in the diagnosis of early gastric tumors especially malignant ones,

at a stage when it is difficult to demonstrate them roentgenographically. The procedure is very useful in the diagnosis of chronic gastritis in which roentgenograms are practically of no value. It should be possible to differentiate the atrophic from the hypertrophic type of chronic gastritis by means of these photographs.

Variations in Acid and Pepsin in Gastric Juice.—While studying the effect of a diet deficient in vitamin B₁, Alvarez and his associates had the opportunity of studying for two months the concentrations of acid and pepsin in the gastric juice removed almost every day from the stomachs of two women and one man. There were marked daily variations in the concentration of acid and pepsin in the gastric juice of the three persons. At times when these variations were great one gastric analysis or even three or four analyses made on successive days would have given a decidedly misleading idea of the usual ability of the particular stomach to secrete acid and pepsin. The variability in gastric secretion was different. The evidence suggests that the greatest degrees of variability are to be found in nervous, impressionable and temperamental persons who react too much to their environment. It is conceivable that the big daily changes in the digestive power of the gastric juice which take place in nervous persons can at times have deleterious effects on the mucous membranes of the stomach and the duodenum.

Prevention of Gas Pains.—Mahoney, granting that the operation is well planned and properly executed, believes that the further step to be taken to minimize abdominal postoperative discomfort is a general solid diet with modifications necessitated by different temperaments and varying conditions. The human intestinal tract is a muscular tube the mucous membrane of which secretes digestive ferments and the motility of which is largely dependent on these ferments and the presence and character of the food material in the intestine. Activity of the liver, the chemical engine of the body and the secretion of bile is greatly influenced by the amount and the variety of ingested food. Whenever starvation supervenes and the usual hospital liquid diet is really semistarvation, the bacteria normally present in the intestine increase enormously and produce large amounts of flatus. If lack of the food to which the upper intestine is accustomed continues for more than a very few

hours, those species of bacteria normally resident in the colon and cecum ascend into the ileum and jejunum and there proliferate, giving rise to huge amounts of gas and to symptoms of toxemia from absorption. Practically all successful medical treatments for colonic stasis appear to depend for their efficacy on lowering or modifying the bacterial content of the colon. The factors in health and normal well being that keep down the growth of these organisms are bile, the hydrochloric acid of the stomach and the digestive ferments, powerfully aided by the peristaltic action of the intestine, which endeavors to move the food taken in by mouth as far as the ileocecal valve in about six hours or less. Necessarily if starvation or semi-starvation is added in the form of the usual hospital "liquid diet" to the systemic shock of an abdominal operation, the secretion of hydrochloric acid, bile and the digestive ferments is decreased, or perhaps these activities are altogether abolished temporarily, and in addition peristaltic action is greatly diminished thus the multiplication of putrefactive and gas producing organisms is favored and everything possible is done to produce abdominal distention in the mild case and adynamic ileus in the severe one. Patients are urged to eat solid food soon after operation, usually the next morning. If not nauseated, they are served a tray the evening of the operative day and encouraged to partake of dry toast, jello, cream of wheat and similar articles. Water is permitted by mouth in such amounts as the patient may desire as soon as the nausea has disappeared. By permitting the early ingestion of water, forcing the feeding of solid food and adding to the feces a bulky ingredient which possesses lubricating properties, other beneficial side effects are obtained. Loss of weight is diminished and the fear of the insertion of the needle for administering fluids is abolished.

Prevention of Postoperative Distention.—In reviewing their eighty-eight cases, which form the basis of their report, Lewis and Axelman find that dimethyl carbamic ester of hydroxyphenyl-trimethyl ammonium methyl sulfite, the physostigmine derivative (prostigmine) prophylactic, has been most valuable in combating the much dreaded symptoms of postoperative distention and gas pains. In comparing these case records with an analogous series prior to their use of the prophylactic, they have found that distention and gas pains have been reduced to a negligible minimum. Prior to its use fully 60 to 75 per cent of their cases would show either subjective symptoms of gas pain or objective signs of gastrointestinal atony or both. Prior to the use of this product the glandular preparations were generally employed, but the results were not sufficiently uniform to warrant continuation of their use. With inhalation anesthetics, the first injection of the prophylactic is given from three to four hours after operation, followed by a second injection four hours later, four injections are given at intervals of four hours the first day after operation. The last dose is followed immediately by a low soapuds enema. This technic has proved effective in preventing postoperative intestinal atony. Most gratifying to the patient and the nurse, as well as the surgeon, is the elimination of repeated high compound enemas for the relief of this painful and annoying condition. With this method of administering the prophylactic peristalsis has been established within twenty-four hours after operation, whereas prior to its use in abdominal cases peristalsis was not established until after a period of forty-eight and in some cases seventy-two hours. Its use has not been attended by any untoward effects by way of systemic or local reaction, the blood pressure is not affected and cardiac action is not interrupted in any way.

Postoperative Lung Complications.—Mettenleiter employed autohemotransfusion in 300 surgical cases, injecting 20 cc. of fresh blood intramuscularly immediately after operation. No lung complications, such as postoperative bronchitis or pneumonia, were observed. Only one patient developed a small thrombotic area in one lung five days after operation. The operations performed were gastro-enterostomies, cholecystectomies, appendectomies, hysterectomies, ovariectomies, herniotomies, thyroidectomies, mastectomies and the like under general anesthesia with gas and ether tribrom-ethanol as base and local anesthesia. The absence of lung involvements indicates that autohemotherapy and not the type of anesthesia applied accounted for the good results. There is sometimes a negli-

gible amount of blood left in the wound, and it has been suggested that the absorption of this blood may render an additional autotransfusion unnecessary. The physicochemical changes in the whole blood and in the serum are so delicate and occur so rapidly that no comparison can be made between blood drawn from a vein and reinjected intramuscularly and blood left in a wound to be absorbed. These two processes are entirely different.

Roentgenologic Observations in Arthritis.—Taylor and his associates selected for roentgen study, because of characteristic clinical and laboratory observations, fifty-nine cases of rheumatoid arthritis, thirty-two of osteo-arthritis, twelve of gout, eleven of gonococcal arthritis, thirty-two of tuberculous arthritis, eleven of rheumatoid spondylitis (Marie-Strümpell) and eleven of Still's disease. Systemic decalcification was present throughout the skeleton in 95 per cent of the cases of rheumatoid arthritis but was best seen in the bones of the hands and feet. Atrophic destruction of bone was noted in 85 per cent of the cases. Marked production of bone, with lipping or osteophytes, was noted in all the cases of osteo-arthritis. Swelling of the soft tissues was present in 67 per cent of the cases of gout, effusion in 75 per cent and atrophic destruction of bone, or punched-out areas, in 83 per cent. In the early stage of gonococcal arthritis, swelling of the soft tissue is usually marked, it subsides within a few days or a few weeks. Local decalcification and slight effusion were noted in 64 per cent of the cases and decreased in the later stages of the disease in which 82 per cent of the patients showed narrowing of the joint space, 36 per cent a moderate degree of active destruction of bone and 45 per cent comparatively early healing with fibrous or bony ankylosis. In tuberculous arthritis, regional decalcification was present in 78 per cent of the cases and local decalcification in 72 per cent, and both persisted through the entire course of the disease. The roentgenologic observations in the cases of rheumatoid spondylitis were similar to those noted in cases of rheumatoid arthritis, except for the anatomic distribution. Systemic decalcification was present in 100 per cent of the cases. The roentgenologic observations in Still's disease were identical with those noted in cases of rheumatoid arthritis. There was however the frequent additional presence of epiphyseal overdevelopment because of the younger age

of the patients. The shadows made by the soft tissues are of the utmost importance in the differential diagnosis of the various forms of chronic arthritis. For example, the swelling of the soft tissues in cases of gout is so characteristically eccentric to the joint that it is possible to make a reasonably certain diagnosis on the basis of this one feature. To determine the degree and extent of changes in the soft tissue, it is necessary to have anteroposterior and lateral views of corresponding joints of the extremities. Atrophic destruction of bone occurs as frequently in rheumatoid arthritis as it does in gout. However, the size of the areas in rheumatoid arthritis is rarely as large as that seen in gout in an advanced stage. Roentgenograms may show little or no change in the early stages of rheumatoid arthritis, osteo-arthritis, rheumatoid spondylitis (Marie-Strümpell), gout, Still's disease or tuberculous arthritis. In the early stages of gonococcal arthritis, however, the roentgenograms are frequently of the greatest assistance in establishing a diagnosis. The appearance of a joint with gonococcal involvement of a duration of six weeks may closely resemble the appearance of a joint with tuberculous involvement of a duration of six months. The results of the study offer considerable evidence in support of the clinical conception that rheumatoid arthritis, Still's disease and rheumatoid spondylitis (Marie-Strümpell) are intimately related. The roentgenologic picture of Still's disease has been found to be identical with that of rheumatoid arthritis in adults, while the picture presented by rheumatoid spondylitis (Marie-Strümpell) differs from that of rheumatoid arthritis only in the anatomic distribution of the articular involvement. Rheumatoid arthritis and osteo-arthritis appear to be distinct entities on roentgen examination. Even in cases in which the two types occur in the same patient or even in the same joint it is usually possible to demonstrate the characteristic changes of each type of arthritis in the roentgenogram. There appears to be some relationship, as yet unexplained, between gonococcal infection and the arthritic changes observed in the metatarsophalangeal joints, certain types of calcaneal spurs and some types of spondylitis. An occasional puzzling case has been encountered in which the presence of a gonococcal infection has apparently modified the appearance of coexisting rheumatoid arthritis. No single roentgenologic feature is a diagnostic criterion for any one type of chronic arthritis.

Respiratory Muscles and Dyspnea—Cournand and his co workers show that, in one particular form of pulmonary fibrosis, dyspnea during mild exertion was apparently due in large part to a hypertonic state of the respiratory muscles and to a disturbance of the normal synergic relations between various groups of them. If their deductions are correct, this disturbance of action of the muscles of respiration takes its place among the numerous other factors which contribute to the causation of dyspnea and adds further to the general concept of dyspnea as a subjective sensation brought on whenever the mechanical apparatus for respiration is unable to provide easily the pulmonary ventilation required by the person's immediate physicochemical and metabolic state.

Variation of Blood and Urine Sugar During Treatment of Diabetes Mellitus—Rogers determined the daily quantitative variation in the sugar content of the blood and in the amount of sugar excreted in twenty-four in cases of diabetes mellitus. In nine cases the variation was slight in seven it was marked enough to interfere with satisfactory treatment when the injections of insulin were given before meals. The variation consisted in an early morning rise in the blood sugar content a parallel rise in the amount of sugar excreted and an afternoon fall in both. Meals did not seem to affect the curves. As a rule the variation was found in young patients with severe diabetes, while older patients with milder forms of the disease often failed to show it. The administration of insulin in anticipation of the early morning rise has resulted in more satisfactory control than could be obtained otherwise but there was no evidence that the total requirement of insulin could be reduced by this method of administration, as stressed by Möllerström. A single dose of insulin given in anticipation of the peak failed to control the condition adequately throughout the twenty-four hours. One patient showing the variation was restudied after a year and similar variability was found indicat-

ing permanence. Accurate establishment of the existence of a definite and constant early morning rise in the blood sugar level should always precede the giving of large doses of insulin in the early morning.

Relationship of Diet, Digestion and Hemoglobin in Hypochromic Anemia Before and After Gastrectomy—Kellogg and his co workers determined the relationship between diet, digestion and hemoglobin production by producing an artificial gastric achylia in the dog by gastrectomy and hypochromic anemia by repeated bleeding. The feeding of beef to dogs having a hypochromic anemia induced by bleeding resulted in a marked rise in hemoglobin output. When, however, the stomachs of these dogs were removed and anastomoses made between the esophagus and the duodenum, the regenerative power of hemoglobin was apparently greatly reduced. Before gastrectomy the output of hemoglobin averaged 1.95 Gm daily, while the dogs were on the beef diet whereas after the operation there was an average output of only 0.08 Gm. It seems probable therefore that the gastrectomized dogs are unable to obtain from beef substances essential to the synthesis of hemo-

globin The weekly withdrawal of from 100 to 200 cc. of blood containing from 10 to 20 Gm of hemoglobin over a period of from three to eight months was necessary before the reserves were depleted—a total of approximately 400 Gm. of hemoglobin. These figures varied somewhat with the individual animal. The amount of hemoglobin appears all the more significant when compared to the total hemoglobin in circulation. Such a dog, at a weight of 16 Kg, may have a circulatory blood volume of 1,200 cc. If his hemoglobin level is 50 per cent, 12×0.42 equals 70.8 Gm of hemoglobin in circulation. The authors' normal dogs on a beef diet may be expected to produce this amount of hemoglobin in five weeks. From the experiments it would appear that, once an anemia is induced and the iron reserves are depleted, this state will persist when normal gastric secretion is lacking. Clinically, this suggests that any process depleting iron stores, such as deficient diet, prolonged and profuse menses and frequent pregnancy, in a patient with achlorhydria may lead to a hypochromic anemia, owing to the failure to get from food and to utilize properly hemoglobin-building materials.

Fate of Sodium Sulfate Injected Intravenously—Bourdillon and Lavietes investigated the fate of sodium sulfate in hypertonic solutions injected intravenously in man as regards its diffusion into body fluids, its effect on some of the electrolytes of blood and its excretion. The subjects were healthy men and women and patients with chronic nephritis. Doses injected ranged from 1.3 to 20 Gm and were in most cases accompanied by sodium thiocyanate. In some cases, potassium thiocyanate was given orally twelve hours before. The sodium ion and the sulfate ion were excreted at the same rate, and the amount of salt injected could probably be recovered totally in urine. The rate of sulfate excretion appeared to be simply proportional to the concentration of sulfate in serum. The figures obtained for the diffusion of sulfate suggest that, like thiocyanate, it is distributed only in the interstitial fluid. The larger doses of sulfate were found to cause usually a dilution of interstitial fluid and a shrinkage of red corpuscles, these phenomena being interpreted as a readjustment of the osmotic equilibrium, necessitated by the fact that neither sulfate nor sodium can penetrate cells.

Parathyroid Hormone in Blood of Pregnant Women—Hamilton and his associates determined the amount of parathyroid hormone in the blood of women by observing the rise of the rabbit's serum calcium after the injection of woman's blood. Of the thirty nonpregnant cases twenty-seven gave either a decrease, no rise or a very small rise in the rabbit's serum calcium. Quite similar results were obtained with the blood from women pregnant less than fifteen weeks. Abnormally great rises were obtained when the blood of women pregnant from fifteen to twenty-four and twenty-four to thirty-four weeks was injected, indicating that during this period of pregnancy an increase in the amount of parathyroid hormone present in the blood is rather common. Toward the end of pregnancy, however, this is much less common, as only three out of thirteen cases showed an abnormal rise, and still more rarely does such a response occur during the lactating period of from six to eight weeks. A curve based on these studies gives an approximate idea of the degree of hyperparathyroidism during different periods of pregnancy. According to Hoffmann the most potent extract can be prepared from the blood of women in the tenth month of pregnancy, the authors' observations indicate that the blood is richer in parathyroid hormone during the seventh month than at any other time, and that in the tenth month the hormone content has usually returned to normal amounts. The curves of a comparison between the calcium requirements of the fetus and the nursing infant and the parathyroid hormone content of the blood of pregnant and lactating women show a rough parallelism on the whole they are both rising until the thirty-fourth week of pregnancy. At that time, however, they diverge sharply, the hormone content returning to normal, while the calcium requirements show a marked increase. It is possible that the increasing demands of the growing fetus with respect to calcium furnish a stimulus to the parathyroids. If this is true, during the last weeks of pregnancy and during lactation this stimulus, for some unknown reason ceases to be effective also during this period there seems to be some tendency toward true tetany with lowering of the serum calcium. It is probable

that in the presence of an abnormal calcium metabolism (as in rickets) or unusual demands on the calcium metabolism (as in pregnancy) an insufficient amount of hyperactivity might also result in tetany.

Methods for Determining Erythrocyte Permeability—Koopman and Falker developed rapid tests for determining the permeability of erythrocytes to any substance that does not react with them. 1 The substance to be tested is dissolved in physiologic solution of sodium chloride. This solution is added to washed erythrocytes. If the cells are permeable to the substance tested, after the substance enters the cells, on the sudden addition of a large quantity of physiologic solution of sodium chloride, hemolysis will take place. Hemolysis will take place only when after the addition of physiologic solution of sodium chloride the difference between the amounts of substance outside and inside the cell causes sufficient pressure within the cells to burst them. 2 When the molar weight of any solute in water equals or exceeds the molar weight of physiologic solution of sodium chloride, the osmotic pressure of such solutes is adequate to prevent hemolysis, excepting in those instances in which erythrocytes are permeable to the solutes. In these instances the rate of hemolysis is directly proportional to the permeability of the erythrocytes. These tests are not applicable to substances which either injure or fix the cells. The authors think that hemolysis is an all-or none phenomenon and that cells hemolyze in hypotonic solutions because of the pressure of the electrolytes in the cells rather than the absorption of water by the cells.

Importance of Oxyntic Cell in Pernicious Anemia—Morrison has been able to demonstrate that neutral red is eliminated selectively by the oxyntic cell of the stomach and that its quantitative excretion runs parallel with the hydro-

chloric acid secretion, i. e., it appears earlier and is excreted in larger quantities in hyperchlorhydrias than in hypochlorhydrias or normal acidities. Neutral red excretion also differentiates true from false achylia, because it appears in the latter but not in the former. These results have been so definite that they have been used clinically, the correlations were made on human beings. His work leads him to believe that the intrinsic factor is a product of the oxyntic cell not only because its secretions parallel one another in the overwhelming majority of cases of pernicious anemia but also because neutral red is eliminated by the oxyntic cell and is at the same time absent only in true achylia. An understanding of the function of this cell may elucidate the mechanism of the production of pernicious anemia.

Precancerous Dermatoses—Missildine and Van Cleave point out that the term "precancerous" is attached to a group of skin manifestations which, if followed to the end product of their development, may result in malignant degenerative tumors of the skin. A great many lesions, such as verruca seborrhoeica and keratosis senilis, although clinically benign, already show malignant degeneration of their cellular constituents when examined under the microscope. Included in this group are keratosis senilis, verruca seborrhoeica, leukoplakia, radiodermatitis, xeroderma pigmentosum, cornu cutaneum, the precancerous melanoses, kraurosis vulvae and Bowen's precancerous dermatosis. With the exception of Bowen's disease, all the foregoing are truly precancerous. Recent investigation tends to show that this disease starts as true cancer cells and should be excluded from the precancerous classification. Other investigators contend that many cases are on record in which malignant degeneration occurred only years after the first appearance of the disease, and that it should continue to be considered precancerous. Only early recognition and proper treatment of precancerous lesions will substantially reduce the incidence of this dreaded disease. It is often impossible to detect lesions of the viscera, but those of the skin or orificial mucosa can be easily recognized and most of them can be treated successfully.

Treatment of Typhoid Group Infections—When the diagnosis of typhoid or of paratyphoid A or B is established, Nyberg gives the patient 10 cc. of a 1 per cent solution of mercurochrome intravenously. He gives one 3 grain (0.2 Gm.) enterically coated tablet of mercurochrome every four hours orally. Eight hours following the intravenous injection of mercurochrome 1,200 cc. of physiologic solution of sodium chloride is given intravenously. Not less than one hour should be consumed in administering it. This treatment is repeated daily for three days, the tablets are given for two weeks longer before stool cultures are made and, if the stools remain positive for typhoid or paratyphoid organisms their administration is continued. Two cases are reported in which treatment was successful.

Prevention and Treatment of Scarlet Fever—Koehler considers the following a successful, safe and practical program for the control of scarlet fever. 1. An intelligent quarantine, based on scientific knowledge and practical experience instead of on tradition and expediency, should be established. 2. All school children less than 7 years of age should be isolated during a serious scarlet fever epidemic for at least six weeks unless such children are immune to scarlet fever as shown by a negative Dick test. 3. All susceptible children in homes with scarlet fever should be immunized as soon as they have passed the incubation period. Statistics show that approximately 25 per cent of all scarlet fever cases are secondary cases in families developing during or after release from quarantine of the primary case. Permitting infectious convalescent scarlet fever patients to return to their homes without the susceptible children in such homes having been immunized first is nothing short of criminal, and yet that is what is being done. 4. The value of throat cultures should be honestly appraised. If a negative throat culture does not always mean that a former patient is no longer infectious, the patient as well as the members of his family should be so informed instead of all being given a false sense of security. At the present time, cultures are not sufficiently reliable to justify unrestricted confidence in them. 5. An intensive scarlet fever immunization program should be in effect for all susceptible children similar to the present diphtheria and smallpox preventive programs. 6. Scarlet fever convalescent serum should be available for the treatment of the more severe types of scarlet fever cases.

Eczematizing Properties of Soaps—Jordan and his associates performed 2,300 patch tests on 115 patients with dilutions of 1 100 and 1 400 of eight widely used toilet soaps and two laundry soaps. Approximately 14 per cent of individuals with normal skins reacted to dilute soap solutions. A positive patch test, therefore, does not always mean that an individual will develop an eczema when exposed to a substance giving such a test. Approximately 50 per cent of the subjects with a dermatitis reacted to dilute soap solutions. Four of seven individuals with other forms of allergy reacted to dilute soap solutions. These results indicate that polysensitivity is common among eczematous patients and that a careful history of allergy is of great importance in the interpretation of patch tests. A soap dilution of at least 1 100 and preferably also a dilution 1 400 should be employed in the performance of the patch test. Mild erythema without papules or vesicles should not be regarded as a positive reaction. The alkali content of soap in solution is of minor importance in the production of eczema. The fatty acids formed on hydrolytic dissociation together with the many miscellaneous ingredients of soaps, most of which are known eczematizing agents, seem the most likely etiologic factors in the production of eczema due to soap. Soaps are definitely the cause of some cases of contact eczema and a contributing factor in many others. Patch tests properly performed and interpreted should be of great aid in the diagnosis of soap eczema.

Treatment of Vincent's Angina with Acetarsone—Maxwell treated fifteen cases of Vincent's infection of the gums or fauces with 10 per cent arsphenamine in glycerin, locally,

plus a mouthwash and gargle of sodium perborate. Results were satisfactory in all but two cases. Twenty-eight patients received acetarsone by mouth, in addition. All made recoveries distinctly more rapidly than when acetarsone was not used. Thirty six cases were treated with acetarsone by mouth, mercural solution usually being employed locally in addition to a sodium perborate mouthwash. Recovery was as rapid as in the preceding group. Ten cases were treated only with acetarsone by ingestion and as a paste gently massaged into the affected part. All improved rapidly. The most rapid recoveries were in this group. One chronic case of gingivitis previously unsuccessfully treated with neoarsphenamine intravenously improved but was not cured with acetarsone.

Acute Gonococcal Perihepatitis—Fitz-Hugh bases his discussion of the syndrome of acute gonococcal perihepatitis in young women on a study of seven cases. The age incidence was 17 to 34, four were single, two were married and one was divorced, five were seen in private practice and two in ward practice. The chief complaint is invariably severe pain in the right upper part of the abdomen. The presenting symptoms are usually so like those of acute inflammation of the gallbladder that this diagnosis has been entertained by experienced physicians in every case that the author has seen despite the relative youthfulness of these patients. The true nature of the process, however may be suspected when the background of the story is brought out viz. during the preceding month or two the

patient has had some low abdominal pain, bloating and nausea, with sometimes slight leukorrhea or dysuria and perhaps a little fever. Usually after a period of a few days to a few weeks quiescence the patient is seized with sudden severe upper abdominal pain, which quickly localizes in the right upper quadrant. It is always worse in front under the rib margin but may also be very intense posteriorly. It is sometimes referred to the region of the right shoulder. Coughing, sneezing, straining, laughing and twisting the trunk make the pain worse. Gaseous distress, belching and nausea are common. Vomiting, malaise, feverishness, headache and night sweats are noted by some. In the acute phase the initial temperature records range from 99 to 102 F. There is always very marked rigidity and tenderness involving the right upper part of the abdomen anteriorly (and sometimes laterally). Limitation of movement of the right diaphragmatic leaflet with signs suggesting right basal pneumonitis and poor aeration of the right pulmonary base may usually be demonstrated. Usually slight tenderness is demonstrable in the lower part of the abdomen. The leukocyte count is normal or moderately elevated. Red cells and hemoglobin are normal or moderately reduced. The sedimentation rate is uniformly accelerated. Smears from the peritoneal exudate are positive for the gonococcus. Smears from the urethra or the cervix were positive for the gonococcus in all cases (except in case 1, in which positive peritoneal smears were obtained). The gonococcus complement fixation test is of no value in these cases. All gave negative Wassermann reactions. Roentgen examination may exclude other conditions such as right basal pneumonitis, gallbladder disease, renal disease and duodenal ulcer. The etiologic agent is obviously the gonococcus, although cultural identification has not been undertaken. The characteristic lesion is a slightly moist inflammation of the peritoneum of the anterior surface of the liver and the adjacent peritoneal surface of the anterior abdominal wall, with injection of the vessels and a grayish flaky or granular exudate. The acute phenomena of perihepatitis begin to subside within a week or two of onset. The outlook is uniformly good, although reinfection of the perihepatic tissues may occur and "violin string adhesions" eventuate. Treatment includes rest in bed, precautions against infection, heat locally, liquid diet and sedatives. Later on the pelvic residue of gonorrhea may require gynecologic attention. Acute gonococcal perihepatitis should be considered in the diagnosis of any case of severe acute pain in the right upper quadrant of the abdomen in young women.

Adverse Results from Bromide Therapy—Kingslev points out that as bromides are used only for preexisting conditions mental changes from their use are superimposed on

psychoneuroses or psychoses. Alcoholism, beginning dementia paralytica, various toxic states, cerebral arteriosclerosis and general debility are predisposing to bromide intoxication. State hospital authorities have recognized a great increase in bromide mental disturbance, probably the result of the present economic depression. Only recently have laboratory methods been devised by which the bromide in the blood may be correctly estimated. The blood bromide may vary from 2 to 300 mg per hundred cubic centimeters of blood. Rapidity of elimination of the drug is important. High concentrations may be found even after discontinuance of it, because ingestion of large amounts extended over a long period, 200 mg soon after its discontinuance means far less than 25 mg from a month to six weeks later. Cases have been reported in which mental symptoms appeared only after withdrawal, and a few observers suggest that withdrawal should be gradual. The general opinion is that it is safe to discontinue the drug suddenly. Custodial or nursing care is always necessary in the more profound states. The bromide must be withdrawn immediately. Thorough elimination should be established and proper nourishment, fluids and sodium chloride from 12 to 16 Gm daily, should be given. About 1 Gm of sodium chloride neutralizes 58 Gm of bromides.

Postmortem Examinations in the Practice of Medicine H. E. Robertson
Rochester Minn—p 370

Serial Pyelography—Silbar and Podlasky worked out a method of serial pyelography based on the precepts laid down by Thomas D. Moore. The apparatus used may be constructed for approximately a dollar and consists of a metal pan and two sheets of lead. The pan and lead sheets should be so designed that they conform to whatever Bucky diaphragm one has in the x-ray department. The measurements are important because it is necessary to center properly in order to avoid grid lines from the Bucky and also to avoid distortion. The technic is that of catheterization of the ureters and kidney, the catheter being inserted to just within the pyelo-ureteral junction. Then 4 cc. of a 40 per cent solution of sodium iodide is used. Sodium iodide in this strength is preferable because it may be used in small amounts, thereby avoiding the distortion accompanying the injection of large amounts of weak mediums. The patient is put in the Trendelenburg position, and 25 cc. of the solution is injected into the pelvis. Then 2.5 cc. is injected as the catheter is slowly withdrawn from the ureter and bladder. A period of two minutes is allowed to elapse before the first film is taken with the patient in the horizontal position. Another one is taken in two and one-half minutes and the last two and one-half minutes later. This may be varied so that one or more of the films may be taken in an expiratory phase and others in an inspiratory phase. If ptosis is to be considered, the patient may have his first picture taken in the Trendelenburg position and the second in the upright, as the apparatus lends itself to any movement of the Bucky. The method is of value because 1. It shows the kidney, ureters and bladder in both respiratory phases. 2. Anatomic parts can be seen filled and emptied. 3. Each kidney and ureter may be safely studied serially and separately, while the other half of the body is protected by lead. 4. Owing to the small areas exposed details of kidney outlines seem to be improved. 5. Permanent visualization of deformities or defects being always an asset, it is possible to be more certain about the presence or location of ureteral strictures or kinks. 6. Exposures to show defects that are suggestive of pathologic changes can be repeated. 7. The patient remains in one position during the examination. This is helpful when it is necessary to make comparison of all serial films.

Encephalography in Childhood Cerebral Conditions—

The members of the staff of the Royal Aberdeen Hospital for Sick Children state that in the interpretation of encephalograms of cerebral lesions the following should be considered: 1 The size of the ventricles, whether increased on one or on both sides. Increase in the size of the ventricles may be of an obstructive nature, owing either to the presence of a lesion which prevents the free egress of cerebrospinal fluid or to failure of the absorbing mechanism, so that the whole cerebrospinal circulation is stagnant. On the other hand, it may be of a compensatory type and result from an attempt to take the place of an atrophic area of the ventricular wall. In the first type, the dilatation will obviously be bilateral and symmetrical, in the second, the dilatation is apt to produce a pouching of one ventricle, over an area corresponding to the loss of cerebral substance, an appearance which has been termed "wandering" ventricle. Space-occupying lesions in the hemispheres will produce lateral deviations of the ventricular system. 2 The size of the basal cisterns, which is increased in cases of failure of absorption of the cerebrospinal fluid. 3 The distribution of the pathways over the hemispheres, whether this is more extensive (for example, encroaching on the occipital lobe) or partly absent, in areas of adhesive leptomeningitis. 4 The width of the pathways over the hemispheres. Normally this is about 3 mm. When convolutional atrophy is present, it may be greatly increased.

Bladder Function in Spinal Injury—Watkins undertook a study to determine the exact behavior of the bladder in cases of injury to the sacral segments of the spinal cord or cauda equina and also in cases of complete transverse lesions of the spinal cord. The investigation revealed clearly the fundamental importance to bladder function of active sacral spinal segments. The influence of these segments below a complete transverse lesion is such as to promote a perfect reflex micturition, which differs essentially from the normal in its entire independence from voluntary control. The behavior of the bladder in lesions of the conus and cauda equina is evidence of a limited degree of function mediated by the peripheral nerve ganglions. This

function is not, however, of itself efficient in evacuating urine from the bladder, for even when the internal sphincter is widely relaxed and the detrusor in contraction there may be no escape of fluid from the bladder. It can only be concluded, therefore, that its peripheral innervation alone determines a very ineffective function of the bladder. It is without doubt the existence of a considerable mechanical resistance in the region of the triangular ligament which deprives this function of the bladder of most of its effect. But it is in virtue of this resistance combined with the patient's ability to expel urine by straining with his abdominal muscles which provides him with the means of living in relative comfort. This patient is therefore in much better circumstance than the patient with a lesion of the transverse cord who, though he has a perfect reflex micturition, is not able to control it.

The Anterior Pituitary and Human Diabetes—To obtain insight into the problem of whether the anterior pituitary plays a part in diabetes, de Wesselow and Griffiths studied the effect of a preceding injection of "diabetic" blood as compared with "normal" blood on the response of the rabbit to insulin. The animals were starved for eighteen hours before the experiment. Inspection of the curves shows that after injection of 10 cc. of plasma obtained from nine nondiabetic middle aged subjects and seven young diabetic patients, all but two of whom had been receiving insulin for some time, there was no appreciable alteration in the form of the blood sugar curve during the period following injection of insulin. In the case of sixteen elderly diabetic subjects with abnormally high blood pressures, the majority of whom were overweight (only three were receiv

ing insulin, the remainder being treated dietetically), however, it would appear that a preliminary injection of the plasma into the animals resulted in an early arrest of the fall in blood sugar after insulin, associated with this premature arrest there was a very definite tendency for the blood sugar to be higher than the control values during the remainder of the experiment. This effect of a diminished fall and a more rapid restoration of the blood sugar after injection of the plasma of these patients was particularly evident in six of the foregoing sixteen patients. During the second period of thirty minutes following the injection of insulin the blood sugar had already begun to rise and after sixty minutes the average blood sugar exceeded the initial value, in these respects the curves obtained after injection of plasma were in sharp contrast to those of the first two groups of patients. The conclusion is that the blood plasma of some elderly, obese, glycosuric patients was found to diminish the hypoglycemic action of insulin in a manner closely resembling that observed by other workers with extracts of the anterior pituitary gland. The knowledge of the metabolic disturbances in diabetes will undoubtedly be considerably extended as the thesis that the anterior pituitary gland and the pancreas act antagonistically in the control of carbohydrate metabolism is developed. It would appear that any alteration in the balance of these opposed influences must lead to abnormal carbohydrate metabolism.

Modified Vanadate Serum Malignancy Test (Bendien-Lowe)—Jones and Woodhouse examined more than 450 serums from patients, approximately half of which were suffering from some type of malignant neoplasm and half from nonmalignant pathologic conditions, together with a few normal serums by the modified vanadate reaction. About 75 per cent of correct diagnoses have been obtained for both classes when all doubtful instances have been rigorously excluded. The results have been examined with regard to the type of precipitation, the age and sex of patients and notes of typical cases are included in which the vanadate test was found to agree with the observations at postmortem examination or operation, in spite of previous clinical evidence to the contrary. Also some cases are described in which the reaction was found to differ grossly from the pathologic observations. Apart from the value of this serologic test in distinguishing between malignant and nonmalignant conditions, considerable success has been claimed (Lowe) in its application for purposes of prognosis following treatment by observing the response of the patient's serum to the surgical or therapeutic measures adopted, as denoted by the zone of precipitation and the type of ratio evinced during a number of successive serum examinations, it is specially valuable as capable of giving evidence of the recurrence of malignant disease before this has manifested itself clinically. In eight cases repeated examina-

tion of the serums were carried out during and after treatment. Although the observations are limited, they seem to afford definite encouragement in this field.

Quinidine Treatment of Auricular Fibrillation—Campbell and Gordon investigated the after-results of treatment with quinidine in two series of patients, one first treated in 1923-1928 and the other in 1929-1934, almost all have been followed up to December 1934, or until fibrillation recurred. Quinidine restored normal rhythm in 64 per cent of 135 cases. In 34 per cent it is still maintained after an average period of nearly four years. In 30 per cent it was restored, but fibrillation recurred after an average period of two years. In 36 per cent quinidine failed to restore normal rhythm or did so for such a short time that it was of no practical importance. Of the earlier series 25 per cent still maintain normal rhythm after nine years, and 39 per cent of the later series after two years. The duration of fibrillation before treatment, the size of the heart and the etiology are all important in estimating the chance of restoring normal rhythm and of maintaining it for a long period. When fibrillation is present without mitral stenosis or a goiter, the selection of cases may be made more leniently, and under favorable circumstances the rhythm may remain normal for ten years or longer. In 39 per cent it is still maintained after an average of five years. In the fifteen who could be classified as having no signs of heart disease except the arrhythmia, it is still maintained in 70 per cent after the same period. After-treatment is not generally needed for more than three months, but, if relapse occurs on omitting quinidine, a second course should be given and, if successful, quinidine should be continued for longer. In those who have relapsed the average period of restored rhythm was more than two years. Thorough digitalization is important before starting treatment by quinidine. Any infection, even a trivial one, may prevent success. Except for the possibility of embolism, which is not a grave risk, serious complications are rare. Satisfactory results are obtained by paying attention to the absence of congestive failure, of a greatly enlarged heart or of a long history of fibrillation. The case is eminently suitable for treatment with quinidine if there have been no signs of failure, if the heart is only slightly enlarged (less than 13 cm maximal transverse diameter in a patient weighing about 140 pounds, or 63.5 Kg), and if fibrillation has been established less than one month. The case is not suitable if there has been gross congestive failure, if any signs of failure persist after treatment with rest and digitalis, if the heart is greatly enlarged, or if fibrillation has been established for six months. The presence of any one of these three usually means that treatment with digitalis should be preferred. When there is mitral stenosis, these conditions must be strictly observed.

Therapeutic Action of Mud Sitz Bath on Erosion of Uterine Cervix. C. Uhma—p 281

Complex Tumor of Female Genital Apparatus—Le Lorier and Isidor describe a tumor of complex cellular structure of the female genital apparatus. It was associated with morphologic anomalies of nonmalignant nature. The most important observations were evolutionary changes of the uterine glandular epithelium, special characteristics of the epithelium of the tubes, the proliferative tendency of the epithelium of the cystic cavities of the cortex of the right ovary, and the nature of the stroma of the neoplastic uterine and peritoneal buds. On the other hand, the evolution toward the epithelial type of uterine, tubular and ovarian serosa, with a tendency to papillary vegetation, was marked. The existence of adenomatous formations of the myometrium, the particular structure of certain regions of the endometrial epithelium and the existence of a complex formation of the ovarian cortex developing in some regions toward an epithelial type and in others toward a fibroblastic type added to the difficulty of the study. These characteristics led the authors toward the conception that the neoplasm represented an embryonal tumor of renal blastoma type and that the indifferent elements constituted both an evolutionary form of uterine and tubular tumors and disemphyoblastic formations. It is, however, impossible to determine the exact manner in which these processes developed.

Immediate Early Cardiac Accidents in Traumatic Arteriovenous Fistulas. Tixier and Arnulf—p 297

Lobectomy and Pneumonectomy in Bronchopulmonary Cancer—Bonniot and Dargent discuss the tourniquet method of Shenstone as a means of performing extensive removal of lung tissue for bronchopulmonary cancer. Because the intervention must be generous, more extensive removal toward the hilus is preferable to subtotal lobectomy or pneumonectomy with a tourniquet. There are two principal objectives, removal of the ganglions and resection of the bronchi well above the tumor growth. In spite of some of the advantages of this procedure, no cancer involving the lobar bronchi can be treated in this way. Cancers of the bronchial stem and the first centimeters of lobar bronchi are unremovable by tourniquet pneumonectomy. This is a common variety of bronchial cancer, but, with the exceptions given, total pneumonectomy with separate ligation of the anatomic elements by the anterior route allows high section of the bronchial tree and is quite successful. The operation is long and difficult but has given good results in the hands of surgeons who have tried radical procedures against bronchopulmonary cancer.

Malignant Intermediary Anemia Clinical Forms P Chevallier—p 467

Primary Benign Lymphocytic Meningitis—The clinical picture of the disease observed in five patients by Livierato and Simoneto is similar to that of tuberculous meningitis. The duration of the disease varied from fourteen to twenty-eight days. Lumbar puncture performed from time to time produced a temporary amelioration of the subjective and objective symptoms. All the patients made a complete recovery without residual signs in the nervous system. The cerebrospinal fluid was negative from a bacteriologic standpoint. Inoculation of guinea pigs for tubercle bacilli also gave negative results. The most remarkable result of the examination of the fluid was the discrepancy between the number of white cells and the quantity of albumin. The lymphocytes were markedly increased, with a tendency to further progression in this direction, while

the albumin was either normal or only slightly increased. Blood cultures and examination of the blood for malaria were negative. Intracranial injection of cerebrospinal fluid into dogs and rabbits gave negative results. Because of these observations the authors believe that the disease lies in the class of meningitis close to that of poliomyelitis or epidemic encephalitis.

Policlínico, Rome

43: 955 1010 (May 25) 1936 Practical Section

- *Pathogenicity of Chilomastix Mesnili A M Cicchitto—p 955
Large Solitary Fibromyxolipomatous Polyp of Rectum Case. D Saleano—p 969

Pathogenicity of Chilomastix Mesnili—Cicchitto states that Chilomastix mesnili is a pathogenic protozoan. In thirty-one patients (white and Negro) suffering from either gastrointestinal or intestinal disturbances the cause of the disease proved to be a pure Chilomastix mesnili infestation. Flies and beetles are the transmitting agents. The administration of antiprotozoal treatment results in disappearance of Chilomastix from the feces of the patient and in recovery of the latter. Chilomastix mesnili may be harmless in certain cases and conditions, while in others, especially in tropical countries, it may cause, alone or in association with other intestinal parasites, gastrocolonic diseases of different intensity. The number of parasites, their type, the constitution, a diminished resistance of the individual due to intestinal, infectious and recurrent diseases, diet, hygiene and climatic and environmental conditions account for the transformation of a harmless into a pathogenic type of the protozoa and also for the evolution of the infestation. The diagnosis is made by the repeated coprologic examination. Two forms, acute and subacute, are the most frequent. The former is of a colonic dysenteriform type, while the latter, which is the most frequent, has the characteristics of a subacute colitis. Intestinal toxemia, which complicates certain cases of Chilomastix infestation, is due to assimilation of toxic products from the intestinal pathologic flora. Certain parasitic associated infestations, such as those with Blastocystis or Endamoeba coli, give origin to the development of an intestinal syndrome clinically similar to that caused by Endamoeba histolytica. The symptoms of the infestation, especially if it is of a pure parasitic origin, in patients in tropical countries are those of a liver rather than an intestinal disease. There is oxaluria in Chilomastix infestation. Eosinophilia is rare. The presence of anachlorhydria is unrelated to the infestation. Chilomastix, as a pathogenic agent for the development of the gastrocolonic disturbances, stimulates the pathogenicity of the intestinal flora, previously normal, and has a slight mechanical, toxic and irritating action on the intestine, which favors the participation of colon bacilli and enterococci in the evolution of the gastrocolonic syndrome. The administration of acetarsone and chiniofon by mouth and in enemas is the specific treatment.

Extracranial Trauma from Accident During Work and Manic-Depressive Psychosis. Case. P. Gori—p 239

"Bulgarian Treatment" in Neurologic and Psychic Sequels of Epidemic Encephalitis—The history, technique and results of the "Bulgarian treatment" in neurologic and psychic sequels of epidemic encephalitis have been reported for the last two years in several Italian journals. The treatment consists essentially in the daily administration of a 5 per cent decoction of Atropa belladonna in white wine, administered three times a day in doses of 5 cc. to patients under 15 years of age and of 15 cc. to patients over 15. The other constituents of the treatment (pills made of Atropa belladonna root and charcoal and the root of Acorus calamus to be chewed by the patient several times a day to stimulate salivation) are useless. The treatment includes also the administration of a hypotonic diet, suppression of stimulants, hygienic practices, gymnastics, reeducation of patients and sometimes orthopedic corrections. The statistics of the Italians are high and include

all forms (slight, moderate and grave) of postencephalic parkinsonism and other postencephalic mental and nervous sequels, in all of which the symptomatic benefit of the treatment was more or less marked, except in certain grave cases. D'Ormea and Broggi resorted to the treatment in fifty cases of neurologic and mental sequels of epidemic encephalitis and report 65 per cent of satisfactory results. The effects of the treatment were in accordance with the intensity of encephalitis and of the sequels and also with the duration of the latter. The neurologic symptoms were more benefited from the treatment than the psychic ones. The disappearance of tremor in cases of average intensity permitted some patients to return to trade work. Oculogyric crises did not develop during the administration of the treatment, although in some cases the doses of Atropa belladonna should be given fractionally to avoid their appearance. Choreic movements and spasms did not improve. The better results of the treatment were in hypertonia and its allied symptoms. Psychic symptoms improved only when they were slight. As a rule grave mental disturbances improve slightly or not at all. The treatment is useless in patients having intense articular deformities and muscular degenerations and it is contraindicated in emaciated, cachectic and openly intolerant patients. The possible dangers of intoxication are controllable by careful determination of the optimal individual dose. The treatment is delicate and should be given only in hospitals with the patient under constant supervision. In some cases there is a tendency to lose weight during the treatment, which may be prevented by the administration of intravenous injections of a lecithin preparation or by treatment with iodine. The best results of the treatment are obtained in patients under the age of 20 and in forms of average intensity and of short duration. The treatment is symptomatic, but it is the best of its type given heretofore. The roots of Italian Atropa belladonna give results as satisfactory as those of Bulgarian Atropa, reducing the cost of the treatment in Italy.

Progresos de la Clínica, Madrid

- Modern Conceptions on Indications for Operation in Renal Tuberculosis L de la Peña—p 341
Rupture of Placenta Hemorrhagic Gestosis and C Avitaminosis J Botella Llusá—p 345
Physiopathology of Digestive Tract J A Sánchez Martínez—p 348
Circulatory System in Diabetes Mellitus. M Quero Morente—p 374
Hydrarthrosis and Pathogenesis of Malignant Tumors L Alvargonzález—p 394

Circulatory System in Diabetes Mellitus—Quero Morente studied the circulatory system in eighty-seven patients suffering from diabetes mellitus, all but fourteen of whom were past 40. In the group of seventy-three patients past 40 the following cardiovascular complications had taken place: aortic atheroma with a frequency of 44 per cent, retinitis 8.2 per cent, renal sclerosis 3 per cent, circulatory insufficiency of the extremities 5.4 per cent, gangrene of the extremities 1.3 per cent, hemiplegia 2.7 per cent, and cardiac decompensation 7 per cent. A syndrome of angina pectoris existed in seventeen patients of the group and was of the painless type in six cases (myocardial infarct without angina). Frank arterial hypertension was found in 28.3 per cent of the cases. Changes in the electrocardiogram were seen in fifty-seven patients of the group (a proportion of 78 per cent): 8.2 per cent of which showed the presence of bundle-branch heart block. The author says that young diabetic patients suffer only from metabolic disturbances, they frequently have diminished blood pressure but no cardiovascular complications. Diabetic patients past 40, on the other hand, have hypertension and suffer from grave cardiovascular complications, especially arteriosclerosis. The most frequent types of anginal and myocardial complications are typical angina pectoris, painless myocardial infarct, angina from coronary sclerosis, vasomotor angina from hypertension and angina from the administration of insulin. The roentgenograms most frequently seen are those of aortic atheroma, increase of the transverse diameter of the heart, mitralization of the heart and either dilatation of the organ or diminution of its size. Heart alterations which fail to appear in electrocardiograms taken with the patient at rest make their appearance in electrocardiograms taken after physical exertion. Both hypertension and diabetes originate in a lesion or a dysfunction of the sympathetic diencephalic centers which are concerned with the

regulation of blood pressure and of sugar metabolism. Arteriosclerosis originates mainly in hypertension. Age and other metabolic disturbances and dietetic disorders are secondary pathogenic factors of arteriosclerosis. Insulin promotes the utilization of blood sugar by the heart of diabetic patients, but, because of the fact that it causes hypoglycemia and increases the output of blood from the heart, a crisis of angina pectoris may follow its administration. This is a warning of the danger of administering insulin in cases of so called comatous collapse (which is nothing more than a sudden myocardial insufficiency) or of myocardial infarct without any angina, erroneously diagnosed as atypical diabetic coma. In the two former conditions the administration of insulin results in aggravation of the myocardial disorder and greatly endangers the patient's life.

Nonregenerative Agranulocytic Anemia Case. A Robiolo and E A Travella—p 245

Paralysis of Hemidiaphragm—Benzádon points out that, according to Goetze's statistics, the motor fibers of the diaphragm pass through the phrenic nerve in only 32 per cent of the cases, and in the remaining 68 per cent through the anastomoses of the nerve, namely, those from the subclavian nerve and, rarely, from an accessory phrenic nerve. The author advises resection of the phrenic, subclavian and accessory phrenic nerves in order to paralyze the hemidiaphragm on the side of the resected nerves. The technic of the operation is easy. It consists in locating and resecting the nerves through an incision from 3 to 5 cm in length, which is made at two and a half fingerbreadths above the clavicle. The resection includes 3 cm of the phrenic and 4 cm of the subclavian nerves. The operation is performed under local epinephrine anesthesia.

Differential Diagnosis in Mute Children Gertrud Lasch—p 78
Growth Process During Nursing Age. E Zeitner—p 95
Gold Therapy of Tuberculous Disorders in Children G Popoviciu and O Mihalescu—p 112

Endogenic Reinfection by Bronchial Perforation—Dietl reports the case of a girl, now 15, who at the age of 8 had given a positive tuberculin reaction without manifestations of tuberculosis. During the spring of 1935 a bronchial perforation developed with circumscribed atelectasis in the left lower lobe. This resulted in endogenic reinfection. The obstructing plug, which contained numerous bacilli, was gradually expelled. The atelectasis subsided and the normal status was apparently reestablished. During the fall of 1935 there developed, as the result of bronchial reinfection, disseminating foci in the left lower lobe and an accompanying perifocal pleurisy. The roentgenogram of one of these foci, with its soft and roundish outline, resembled the usually isolated foci found as a rule in the infraclavicular region and generally referred to as early infiltrate. In this connection, the author points out that the development of the so-called early infiltrate, which at present is generally regarded as the beginning point of the phthisis—that progresses from the apex in the caudal direction, has been ascribed by some to a bronchial perforation. In view of this, he raises the question whether the round infiltration in the case under consideration might be an early infiltrate. He thinks that the localization in the lower lobe does not necessarily exclude it and that its appearance favors it. Most early infiltrates (but not all) break down, but in the reported case the infiltrate showed no sign of breaking down. Moreover, the girl had no fever and felt well. The author concludes that it cannot be said definitely that the focus is an early infiltrate, but neither can this be definitely denied. The case demonstrates the mechanism of the formation of a new focus by way of endogenic reinfection.

Carbon Monoxide Poisoning—According to Litzner, the entire vascular system is more or less involved in cases of carbon monoxide poisoning. The general vascular atony should be counteracted by medicaments for the peripheral circulation. The author thinks that the changes in the heart itself have not been given sufficient attention. He shows that, as the result of the impairment of the vascular supply of the heart, temporary changes develop and also occasionally permanent organic lesions, which may involve the musculature as well as the cardiac conduction system. He describes a case in which sinus bradycardia, arrhythmia and ventricular extrasystole appeared after carbon monoxide poisoning. These changes disappeared again in the course of several weeks. There also existed a dilatation of the left ventricle. The author advises that cardiac changes should be watched for in cases of carbon monoxide poisoning.

 *Treatment of Flatfoot by Exercise. O Kolb —p 774

Beriberi Produced by Excessive Consumption of Sugar—After pointing out that beriberi occurs chiefly in eastern Asia and that its classic form is practically unknown in Europe, Stepp and Schroeder mention as the chief symptoms manifestations on the part of the nervous system, paralyses, severe sensory disturbances, generalized edema, cardiac dilatation and gastro-intestinal disturbances. They report the history of a patient with severe retention of water and cardiac dilatation, in whom they finally discovered a relative B₁ avitaminosis. The problem was solved when it was learned from the wife of the patient that for about a year the man had consumed daily from 500 to 1,500 Gm of sugar. The intravenous administration of vitamin B₁ was followed by diuresis and the patient was freed from his severe thirst. Whereas in the water tests that were made before the medication with vitamin B₁ the patient had retained large amounts of the fluid, he now eliminated the entire amount. The normalization of the water exchange was accompanied by an improvement in the general condition. The edemas and the dyspnea disappeared. The examination of the patient's carbohydrate metabolism failed because he had consumed secretly 500 Gm of sugar and later had an attack of hypoglycemia. In discussing the pathogenesis of B₁ avitaminosis following excessive intake of carbohydrates, the author cites experimental studies on animals which proved that the addition of pure dextrose to the ordinary foods may produce a B₁ avitaminosis. After showing that in the reported case the disorder was actually a relative beriberi the authors say that, although B₁ avitaminosis has been produced in animals by the administration of large amounts of sugar, such cases have not been reported as yet in human beings.

Nonspecific Treatment of Allergy and Protection of Liver—Kämmerer says that the so-called shock organs are not the same in the different species of animals so that the shock reactions differ. In guinea-pigs, spasms develop in the smooth musculature of the bronchi, in rabbits the pulmonary arteries develop spasms whereas in dogs the liver is the shock organ during an anaphylactic attack the liver is congested and there is blood stasis in the abdominal viscera. It is suggested that the capillary endothelium of the liver is affected by the shock and that the shock is elicited by the encounter of an antigen and a reaction body in these cells. In this process the liver cells are supposedly greatly impaired so that large quantities of histamine-like substances develop. The author assumes that in human subjects it is likewise the liver which

plays the chief part during shock or during the defense against foreign antigen. To be sure, the site at which the antigen enters the organism doubtless determines the predominance of the one or the other shock organ. With antigens that enter the human organism by way of the respiratory tract, the capillary endothelium of the lung is doubtless severely involved, whereas the liver is the most severely affected organ in case of food allergy. In case of severe allergic reactions, several organs are involved, as is indicated by the appearance of asthma in case of allergy for egg white. The author shows that investigators on food allergy have demonstrated that enteral sensitization is largely dependent on the functional adequacy of the liver in the digestion of foreign proteins, and that insufficiency of the liver is one of the chief causes of an allergic diathesis. He shows that the liver has a regulatory function in the water exchange and that water tests are a more reliable indicator of the hepatic function than are levulose and dye tests, moreover, the water exchange is frequently impaired in patients with allergic disturbances. He advises that patients with allergic attacks should be subjected to various hepatic tests and that in the treatment of allergic disorders the liver should be given attention. He stresses the importance of dietetic measures, particularly those providing an adequate glycogen supply of the hepatic cell. On the other hand, the diet should restrict animal proteins, alcohol, salt and condiments. He thinks that Carlsbad, Vichy and other waters may prove helpful and that high calcium and vitamin contents of the diet are important.

Treatment of Flatfoot by Exercise—Kolb calls attention to an exercise first recommended by Silberhorn, which aims at strengthening certain muscles and is most effective with a simple apparatus devised by Silberhorn. The legs must be held apart for a distance of from 15 to 20 cm. This is accomplished by heel holders and a board that is placed between the legs below the knees. The toes are placed in holders to which a ring is fastened, which in turn is hooked onto spiral springs that draw the toes outward. The exercise consists in drawing the toes of the two feet together and then again yielding them to the traction of the springs. During the time the toes are drawn inward, the inside of the foot is lifted up and the sole of the foot is arched. That the muscles which elevate the arch of the foot are greatly influenced by this exercise is indicated by the fact that they are extremely painful at the beginning of the exercises but later this pain disappears. The treatment is most effective in children, but even in adults it is helpful in counteracting the difficulties caused by flatfoot, in that it strengthens the muscles.

Hemorrhagic Diathesis and Vitamin C—Armentano points out that the spontaneous hemorrhages play an important part in C avitaminosis, especially scurvy, and that, because of this, vitamin C has been used in the treatment of disorders that are accompanied by hemorrhagic tendencies. He shows that there are a number of intermediate stages of hypovitaminosis between the state of normal vitamin supply and scurvy. The reduction of the capillary resistance and of the quantity of cevitamic acid in the urine indicates severe degrees of hypovitaminosis. Milder forms of vitamin deficiency can be detected only by means of tolerance tests with vitamin C. To be sure not every reduction in the capillary resistance indicates a hypovitaminosis. The hemorrhagic tendency of diabetic patients and apparently also a large number of hemorrhagic diathesis cannot be ascribed directly to a deficiency in cevitamic acid. In tests on normal persons it was found that the administration of cevitamic acid does not increase the number of thrombocytes this applied also in some pathologic cases. The author points out that, in the course of infectious diseases and after

a one-sided diet has been taken for long periods, a hypovitaminosis may develop that does not necessarily become manifest in a hemorrhagic tendency. In such cases, adequate supplies of vitamin should be given.

Influence of Copper on Carbohydrate Metabolism—Schnetz studied the influence of orally administered copper on the blood sugar content. He found that in normal persons epinephrine hyperglycemia as well as dextrose hyperglycemia could be inhibited by the daily administration of 20 mg of copper (in pills). Equivalent quantities of iron were found to exert no influence on these forms of hyperglycemia. The inhibiting effect of copper in the induced hyperglycemia as well as the anti-infectious, antianemic and roborating actions of copper induced the author to try copper medication in several cases of severe diabetes mellitus. He found that with copper therapy the doses of insulin could be greatly reduced, for the sugar content of the blood and the urine declined and the general condition was greatly improved under the influence of copper. The inhibiting action of copper seems to influence only the increased sugar content, for the normal sugar content is neither increased nor reduced by copper medication. The fact that only the increased sugar content is influenced seems to indicate that the effect of copper medication is largely due to the action of the liver. The author gained the impression that individualization of the dosage is highly important in copper medication of hyperglycemia and that the action of copper is restricted to certain degrees of hyperglycemia. In two cases of mild to average severe diabetes, the author found that insulin therapy could be entirely replaced by copper treatment.

*Estrogenic Substance in Treatment of Milk Fistula and Mastitis W Lindemann—p 1045

*Experimental Adenomyosis Following Interruption of Pregnancy by Curettage in Rabbits W Zaleski—p 1046

Recognition of Overdue Pregnancy—Von Brücke describes the case of a woman who came to the clinic when, according to her statement, 321 days had passed since the last menstruation. She stated that during the last two weeks the fetal movements had become less frequent. However, since the fetus did not show excessive size and since there were no irregularities in the fetal heart action, the woman's statement seemed to lack definite proof and a cesarean section was not suggested. Attempts were made to induce labor by means of hot baths, enemas, castor oil, quinine and pituitary extract, but without success. These measures were continued for two days, but on the third day the fetus died. On the following day labor pains set in and the delivery was terminated by cranioclasia. The author stresses the great importance of roentgenoscopy of the fetus in determining the degree of maturity in cases in which prolongation of pregnancy is suspected but in which the size of the fetus does not indicate it. In the reported case a roentgenogram of the dead fetus after birth revealed that the bone nuclei of the knee joints were much larger than is the case in infants that are born at the normal term, for they were about as large as those found in the second month of life. As past-term infants often die during birth, the author says that a cesarean operation may be advisable but that the medicinal induction of labor should as a rule be tried first.

Estrogenic Substance in Treatment of Milk Fistula and Mastitis—Lindemann points out that incisions in cases of mastitis often result in the development of milk fistulas. He reports the case of a woman in whom a milk fistula with profuse secretion proved refractory to all therapeutic measures. In the hope of being able to influence the condition by hormone action, the author injected 50,000 mouse units of estrogenic substance intramuscularly. Two days later, the profuse milk secretion showed a considerable decrease and the accompanying eczema a great improvement.

Adenomyosis Following Interruption of Pregnancy by Curettage—Zaleski subjected ten nonpregnant rabbits to laparotomy, in the course of which he scraped one horn of

the uterus with a sharp curet but left the other unimpaired. After from sixty to ninety days he made microscopic studies on the uterus of these animals, but he never detected signs of an adenomyosis. In a second series of experiments he interrupted the pregnancy of seven rabbits by means of curettage. Examinations made from fifty to 240 days later disclosed in four of the seven rabbits foci that greatly resembled adenomyosis. He concludes that his observations give experimental proof that in rabbits the interruption of a pregnancy by means of curettage often results in adenomyosis. Although he admits that animal experiments are not applicable to human subjects without restriction, he thinks that under certain conditions curettage of the human uterus may likewise cause the development of adenomyosis. He recommends clinical observations in this direction.

Action of Diathermy in Cases of Projectiles in Brain H Hoff and P Schilder—p 541

Protein Therapy in Suppurating Infections F Schurer von Waldheim—p 543

Therapy of Thrombophlebitis and Thrombo-Embolism—Ewald evaluates the various remedies that have been suggested as prophylactics and mentions some predisposing factors. He calls attention to the fact that many of the patients who die as the result of an embolism are of a short, rather obese, type. Cachexia, on the other hand, predisposes a patient to thrombo-embolism. The diagnosis of the mild, deep venous thromboses, which lead to embolism most frequently, is rather difficult. But these thromboses should be searched for every day, particularly during the first few days after the operation, as they are most likely to develop during this time. To be sure, embolisms occur even in the course of the operation, and in these cases the thrombosis can hardly be ascribed to the operation. The thrombosis may appear with and without signs of inflammation. Recognition is especially difficult in the latter case and careful examination is necessary. Once thrombosis has been recognized, the chief effort should be to prevent the detachment of the ascending clot, for this, and not so much the obstructing portion, presents the danger. Complete rest and correct bedding are of great importance. The author recommends support for the lower part of the legs, so that the knees are bent at a right angle, and elastic bandages. The bandage must be put on with extreme caution. If the embolism has produced a pulmonary infarct, the treatment must follow the rules of internal medicine, but, if the embolism obliterates the pulmonary artery, delay involves danger. Since Trendelenburg recommended excision of the thrombus from the pulmonary artery, the decision on the proper treatment has become rather difficult, because it happens that patients who seemed dead recover without intervention, on the other hand, by an expectant attitude the right time for an intervention may be missed.

Therapy of Thrombophlebitis and of Thrombo-Embolism C. Ewald—p 574

Treatment of Tuberculous Hemoptysis with Parathyroid Extract—According to Fang, most clinicians differentiate two types of tuberculous hemoptysis, the type that results from the rupture of a larger pulmonary vessel (rhesis) and the type that takes place through the intact vascular wall (diapedesis). Rhesis is frequently refractory to all therapeutic interventions and ends fatally, but in some instances pneumothorax treatment, phrenicectomy or thoracoplasty may be helpful. In diapedesis, however, in which a disturbance in the coagulation of the blood plays a part, hemostatic remedies are advisable. The favorable results produced by parathyroid extract in various types of hemorrhages induced the author to try this treatment in pulmonary hemorrhages of tuberculous

patients He reports his observations in 102 cases The success of the treatment was complete in eighty-one cases, moderate in eight, doubtful in nine and failed completely in four cases of rheixis The usual mode of administration was by intramuscular injection (rarely intravenously) As a rule, 1 cc was given three or four times daily The injections were usually continued for another day after the hemorrhage had ceased They were always well tolerated

Blood Chlorides in Malariotherapy—Klemperer, at the suggestion of Wagner-Jauregg, studied the chloride content of the blood of patients undergoing malariotherapy Tests were made on the whole blood as well as on the serum She says that the chloride content of blood and serum was reduced in only a small number of the examined patients Moreover, this reduction is comparatively slight, so that it can readily be compensated by the reserves of the organism

*End Results in Gastric Surgery with Especial Reference to "Resection for Exclusion." S Friberg—p 157

Embolectomies—According to Hindmarsh and Sandberg, forty-five embolectomies for embolism of the large vessels of the extremities were performed at the Maria Hospital in Stockholm between 1912 and 1934 Thirty of these were performed by Einar Key, who was the first in Sweden to perform a successful embolectomy, twenty-three years previously A follow-up study was made of forty patients, on whom forty-five embolectomies were performed There were fourteen men and twenty-six women Chronic heart disease was the cause of embolism in 77 per cent of the patients, in six embolism complicated an operation, an obstetric delivery or an infection, and in three the cause was not ascertained Adequate circulation in the involved limb was reestablished in eighteen patients (58.1 per cent) operated on within the first ten hours after the onset of the symptoms Normal circulation was reestablished in five (35.7 per cent) of fourteen operated on after this period Of the forty-five embolectomies, recovery occurred in seventeen (37.8 per cent) In six other cases the local effect was successful but the patients succumbed to the original disease. Thus the embolectomy alone was successful in twenty-three cases (51.1 per cent) These patients have regained normally functioning limbs The operations failed to save ten patients from a subsequent amputation of the limb Two thirds of the patients on whom a successful operation was performed did not survive the ten year limit. The authors emphasize that the high early and late mortality rate is due not to the operation of embolectomy but to the original disease

End Results in Gastric Surgery—Friberg submits a follow-up study of 398 cases of gastroduodenal ulcer in which operation was performed at the Västerås and Köping (Sweden) hospitals Particular emphasis was laid on the results in sixty-eight cases in which the operation of "resection for exclusion" had been performed In this procedure, advocated principally by Finsterer, no attempt is made to resect the ulcer situated in the duodenum or in the pylorus in order to avoid injuring the pancreatic or the common bile duct in the case of a low duodenal ulcer, or because of mechanical difficulties presented by a large callous ulcer The antrum and a portion of the corpus are resected with the view of lowering the acidity The continuity is restored by an end to side gastrojejunostomy The primary mortality for this group amounted to 4.4 per cent, while that for radical resection was 12.6 per cent. There was no instance of a recurrent or of a peptic jejunal ulcer in the group of "resections for exclusion" A permanent cure was obtained in 87.7 per cent which is as good as that obtained by the method of radical partial gastric resection and better than that obtained by the operation of gastro-enterostomy No difference in the results was observed in the cases in which the pylorus was resected and those in which it had been retained.

- *Celiac Disease Mildrid Andersen—p 434
Blood Picture After Thoracocautery P Mourier—p 441

Celiac Disease—Andersen describes the case of a boy, aged 8, small for his age, red haired and freckled, with a history of digestive disturbances since early childhood and pathologic amounts of fat in the feces The fasting blood sugar is normal, the blood sugar curve is low after the oral tolerance test with dextrose, abnormally short after intravenous tolerance test and normal after injection of epinephrine Roentgen examination shows passage too rapid in the small intestine and too slow in the large intestine There are achylia, marked anemia, low blood pressure, flabby musculature, meteorism of the abdomen and retarded development of the ossification centers. The diagnosis of celiac disease is based on the increased fat elimination and the appearance of the feces before remission and on the typical low blood sugar curve, the symptom complex for idiopathic steatorrhea (celiac disease, tropical and nontropical sprue) Anemia, usually hypochromatic, is constant, and retarded growth is also an important symptom The disorder occurs predominantly in blond children, in Fanconi's twenty eight cases, twenty-four of the children were blond, three red haired and one dark. The course is typically remittent, markedly chronic and capricious The mortality is about one third, death being due sometimes to cachexia, more often to complications The author is inclined to regard the intestinal disturbance as primary The abnormal blood curve, low blood pressure, pigmentation, muscular weakness and the delayed appearance of ossification centers and retarded growth apparently point to an impaired function of the anterior lobe of the pituitary, the thyroid and the adrenals, the intestinal disorder is thought to cause disturbances in the little known endocrine apparatus of the duodenum, leading to interruption of the correlation of the organs of internal secretion.

THE COMMON COLD

CHAIRMAN'S ADDRESS

WILLIAM J KERR, M.D.
SAN FRANCISCO

It is my purpose to discuss the disorder which in our time bears the designation of "the common cold." This malady directly accounts for frequent periods of indisposition and incapacitation of people everywhere and, through complications, results in untold suffering and sacrifice of human life. The economic loss in time and in wages is greater in this condition than in any other disease that affects the population at large.

When attempting to define the common cold, one is at once beset with difficulties. The terms "cold in the head," acute rhinitis and coryza are used interchangeably. The layman uses the term "a cold" to designate almost any type of inflammation in the body but more often for any respiratory disturbance from "cold in the head" to pharyngitis, tonsillitis, laryngitis, tracheitis, bronchitis, sinusitis, hay fever and disease of the middle ear. The physician likewise may use the term "a cold" rather loosely to designate inflammations in any part of the respiratory tract and accessory structures. The condition is often mistaken for influenza, or la grippe, particularly during epidemic periods of the latter. Influenza is frequently mistaken for a "simple cold," and serious complications may result from lack of proper treatment. The most frequent confusion is with hay fever. The basis of differentiation between inflammations due to some infectious agent and those due to other causes is not well established. Reactions to foreign proteins (hay fever) and chemical irritants and other less well defined physical and emotional disturbances are recognized but not always differentiated.

PATHOGENESIS OF THE COMMON COLD

A workable definition of the common cold could be stated as follows: an acute disorder presenting its most obvious symptoms in the nasal passages, occurring most frequently in the fall and early spring in temperate climates, and attacking great numbers of the population almost simultaneously. The attack is initiated by general sensations of coldness or chilliness. The local symptoms in order of appearance are sneezing, a profuse watery nasal discharge and stuffiness in the nasal passages. At this stage the subject passes increased amounts of pale urine of low specific gravity.

From the Department of Medicine, University of California Medical School.

Address of the chairman of the Section on Practice of Medicine, read before the joint meeting of the Section on Practice of Medicine and the Section on Pharmacology and Therapeutics at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

At the onset the nasal mucous membranes are drier than usual, and there is a sensation of irritation in the upper air passages. There may be headaches and malaise. When the subject complains of general sensations of coldness or chilliness the skin is cold and blanched and "goose-flesh" appears readily on exposure. The dryness of the nose gives way in a few hours to a copious secretion of irritating watery fluid, accompanied by paroxysms of sneezing. At this stage the mucous membranes of the nose, especially on the turbinates, are swollen and injected. There is almost always a reduction of the oral temperature in the early part of the course, in my experience for the first twenty-four to forty-eight hours fever rarely occurs, in uncomplicated cases. The stuffiness of the nose increases and soon causes practically complete obstruction to the passage of air. After two or three days the irritating secretions gradually become thicker and more cloudy because of the exfoliation of cells from the injured mucous membranes. The secretions tend to become purulent when the obstructed accessory nasal sinuses begin to drain. The subject may be obliged to breathe through the mouth during the stage of congestion and obstruction.

When recovery takes place, the general sensations of chilliness and lack of perspiration associated with a constriction of the peripheral vascular system give way to feelings of warmth and returning moisture to the skin. The peripheral vascular system resumes a more normal functioning state and the urine now becomes more scanty and highly colored. The course of illness is variable in length but as a rule the symptoms terminate in a few days (from three days to two weeks), depending on the effectiveness of treatment and the occurrence of complications. A fact usually lost sight of is that the common cold runs its course in from three to five days. The complications prolong the period of recovery and are confused with the initial disorder.

The lack of a lasting protection against subsequent attacks of the disorder is characteristic and unique.

Some may take issue with this definition of the common cold. It should be noted that no etiologic factors have been specified. These will now be discussed.

Until about the turn of the century it was generally accepted by medical authorities that exposure to chilling, such as by drafts, wet feet and damp clothing, was the cause of the common cold. Subjects who became overheated and perspired freely were thought to be more susceptible to overcooling. Fatigue and feasting also were considered as etiologic factors. Toward the end of the last century the development of knowledge in bacteriology was rapid and enthusiasm carried many workers far afield. The medical profession seemed willing to accept a bacterial origin for most diseases,

including lead poisoning, cancer, chronic arthritis, beriberi and pernicious anemia. That supposition overran fact we can now testify. On investigation of the upper respiratory passages, a host of bacteria were found, each of which, in turn, came under suspicion as the cause of the common cold. After much study of these micro-organisms it was concluded that they were not primary etiologic factors, it was assumed that if they contributed to the symptoms in any way it was only in a secondary capacity. The "soil" was thought to be prepared in some fashion for the invasion of organisms already present. Obstruction of the atria of the accessory nasal sinuses was thought to provide suitable conditions for bacterial growth behind the obstruction.

On the mistaken hypothesis that the common and visible bacteria discovered in the respiratory passages were of etiologic significance, the medical profession and the public have used many types of respiratory or "cold" vaccines for the prevention of the common cold. There is no proof that such vaccines exert any specific protective action, and if there is any value in the procedure it is likely that immunity is enhanced against the action of these organisms only as secondary invaders or for some other reason still undetermined. Perhaps the only virtue in the periodic use of such vaccines lies in a nonspecific action of foreign protein on the autonomic nervous system. This action is demonstrated in testing the peripheral vessels for spasm, and its effects may be more enduring than is known at present. If the peripheral vessels are more permanently relaxed, the effects of cooling may be minimized.

In recent years Dochez has advanced the hypothesis that the common cold is due to a filtrable virus and in support of this view has presented data on careful and extensive experimental study. It is quite likely that this worker is able to transmit and to grow in tissue culture an agent which produces symptoms resembling those of a common cold, but that this agent is the universal primary cause of the common cold may be doubted. The question may be raised: Do the products of disintegration of the tissue cultures themselves cause sufficient irritation to reproduce the local symptoms of a "cold"? Likewise can molecular substances akin to ferments and bacteriophage, standing somewhere between organic chemical substances and living things be excluded? May they not under suitable cultural conditions in mediums containing mammalian tissues be susceptible of reproduction in experimental subjects and animals and give local symptoms?

The recent studies on influenza by Laidlaw, Andrewes and Smith in England and Shope and Francis and Magill in this country mark an advance in the study of respiratory diseases. A filtrable virus appears to be the etiologic factor. At last it may be possible to isolate one of the agents that attacks the mucous membranes of the respiratory tract. The development of immune reactions in those recovering from influenza is demonstrated. This should make it possible to identify influenza and narrow the group for further consideration. There is apparently no close immunologic relationship between the virus described in influenza and that reported by Dochez in the common cold.

The science of bacteriology deals with the small living things found in our environment and with the biologic reactions to them which is called immunity. Is it not evident that there are other environmental factors which influence our existence? To continue life as a biologic unit we must be in balance with our environ-

ment. Our means for protection are multiple but our ability to adapt ourselves to changing conditions of temperature and humidity is among the more remarkable of our protective mechanisms.

It is unfortunate that so much effort has been expended on the bacteriologic study of the respiratory diseases and so little on the study of fundamental physiologic mechanisms that may be at fault. Those of the greatest interest are in the nose and the skin. The remarkable structure called the erectile tissue situated on the turbinate bones in the nose lies in the direct pathway for the air entering the nasal passages. It is richly vascular and is intimately connected with the autonomic nervous system. Its chief function is to prepare the air for the deeper reaches of the respiratory tract, through its power to warm and humidify the air. This special tissue is remarkably adaptable and highly sensitive to many influences. When it fails to function properly, the unprepared air may injure the tissues beyond and probably does so, as will be discussed later. The mutual relationships of this mechanism with the functions of the skin, lungs and kidneys in regulating heat and water in the body are not completely understood, but that they are important cannot be questioned.

It may be assumed from present knowledge that there are a number of agents which may cause disturbances in the erectile tissue of the nose. One need mention only the rhinitis seen in iodism, the hay fever caused by pollens and danders, and the local effects on the nasal mucous membranes of contact with fumes, dusts and other irritating substances. War gases and dusts from the prairies are examples of the last group. Deflection of the septum, which brings the swollen mucous membranes in one passage in close apposition to the lateral wall, may provoke unilateral symptoms. In a number of the infectious diseases, notably syphilis and measles, marked rhinitis may occur. Influenza does not, as a rule, begin with an acute rhinitis. In this disease the pharynx is usually reddened and the nasal passages may be irritated, but obstruction and abundant secretion are uncommon.

It is well known that exposure to cooling after being overheated, or excessive cooling of the extremities particularly after wetting of the feet or sitting in a draft will in most subjects cause nasal obstruction, sneezing and watery secretions. Of this there can be no doubt from the experience of generations of people everywhere. The faulty methods of heating our homes, offices and workshops, with lack of proper humidification, result in atmospheric conditions that overwork the nasal humidifier and irritate the mucous membranes.

It may be assumed that anything which causes congestion of the erectile tissue and thereby obstructs the nose will cause sneezing and the outpouring of a thin, watery secretion which is not specific for the causative agent. Most of the confusion in diagnosis has come because of the failure to recognize this fact. When the patient presents himself with rhinitis, there is no characteristic symptom by which one type can be readily distinguished from another. A "cold in the head" means only that he has a rhinitis or coryza. It may be stated, advisedly, that there are also no absolute physical guides in the differential diagnosis of rhinitis. It would perhaps, interest physicians and specialists in diseases of the nose and throat to examine patients objectively as we have done, without recourse to histories, and to follow them through attacks of rhinitis. No agreement can be reached as to what is a common cold and what is an allergic state in the nose from the physical exam-

ination alone. This difficulty is to be anticipated since the objective signs result from disturbances in a tissue that has a well defined physiologic reaction. A subject with hypersensitiveness to pollens or other allergens may also experience reactions to other agents, be they dusts, viruses, physiologic alterations in the mucous membranes from exposure to cold, or other causes.

The general symptoms of the common cold are as important as the local symptoms. These are associated with constriction of the vessels in the skin, with coldness, and with decreased sweating which results in the increased secretion of urine that is pale and of low specific gravity. Cold weather does not contract or irritate the bladder, it only makes the kidneys a substitute for the skin as an outlet for water from the body. Fever is not an early sign, and, as I have shown, the temperature is usually subnormal for the first twenty-four to forty-eight hours.

If the known infectious diseases that produce respiratory symptoms, such as measles, syphilis and influenza, are excluded, it will be found that there remains a very large group of acute disorders which may be classed as rhinitis. Through history and skin testing a considerable number of reactors to allergens can be recognized. Among these persons will be found many who suffer from symptoms of rhinitis during the fall and spring months when colds are frequent. They may have increased susceptibility to changes in temperature as well as hypersensitiveness to allergens. Subjects with chronic disorders of the sinuses and with deflected septums likewise have symptoms of rhinitis when sudden changes of temperature occur. The majority of the population, however, experience from two to four "colds" a year, and it is not clear that they belong to any of these groups.

It is my opinion that they develop a type of rhinitis which may be designated as the common cold, resulting from exposure to sudden cooling of the body due to faulty adaptation to their environment. The rhinitis arises through swelling of the nasal mucous membrane when the periphery contracts on cooling of the skin. Individual differences in the capacity to react to cooling may account for the frequent occurrence of colds in some people and the infrequency of attacks in others. The great prevalence of colds in the fall months may be explained by lack of protection against overcooling due to peripheral vascular relaxation during the summer months. The inability of residents in the tropics to adjust themselves quickly to temperate climates is an expression of extreme peripheral relaxation. In the spring months the deceptive warmth of a sunny day leads to untimely shedding of warmer clothing, and overcooling may result. The excessive amount of heat required to change water from the solid (ice) to the liquid state should also be taken into account. The familiar expression that the blood gets thicker in the winter months is probably based on the observation that the cold air is then tolerated better, and this is almost certainly due to the stimulation during the cold weather, of the local vascular reflexes to cooling.

The clinical features of the common cold are not characteristic of an infection. There is ordinarily no fever in the early stages. In a given individual the clinical course is usually the same in successive attacks beginning usually with rhinitis and followed by sore throat, laryngitis, tracheitis and bronchitis. In most subjects the rhinitis appears first, and in many there is a gradual descent in the respiratory tract. These events may be explained by conditions existing in the indi-

vidual. If the nasal mucous membranes fail to function, the unprepared air injures the deeper tissues and symptoms arise from inflammation in the pharynx (including the tonsils) or in the larynx, trachea or bronchi. It is not necessary to assume that bacteria or viruses play any part in this sequence of events. It is well known that irritating gases, dusts and liquids may be primary causes of injury to the respiratory mucous membranes. Mouth breathing, as a result of obstruction of the nasal passages, permits unprepared air to injure the mucous membranes of the mouth, tongue, pharynx and lower respiratory passages in patients, and it is reasonable to suppose that it does so, also, in persons suffering from rhinitis.

Studies that have been made in our clinic show the well known seasonal prevalence of the common cold, but careful statistical analysis by weekly periods fails to show any positive correlation with the cooling power of the air. It is possible that, if all the circumstances could be controlled and analyzed, such a correlation would be shown to exist. Daily reports would probably be of greater significance. To date, no surveys on the incidence of the common cold have been of great value because of the difficulties inherent in establishing the diagnosis and in securing the complete cooperation of any large group of the population for a long period of time.

During the past few years, in an investigation undertaken with my associate John B. Lagen, attempts were made to reproduce the common cold so that the physiologic mechanisms involved could be studied. We selected groups of subjects who were known to have frequent attacks of the common cold and who had not suffered from it in recent months. We placed them in a room where ideal environmental conditions for comfort could be maintained (temperature 71° F, humidity 55 per cent). We exposed successive groups to different individuals suffering from the common cold in the acute stages. The exposure was intimate and continued for several hours in the groups studied early in our investigations, but in the groups studied later, in addition to intimate contact, fresh secretions were injected into the conjunctival sacs, and thermometers and drinking glasses were contaminated with the secretions. In a total of nineteen subjects in five groups, and exposed to five sufferers, not one positive result was obtained. This does not prove that there is no type of rhinitis which is contagious, but it does suggest that colds are not so readily transmitted as many assert. Acute colds are nasty, but the element of fear in the presence of the miserable sufferer is one of our modern bogies. In families, on numerous occasions, only certain members suffer from repeated colds. Isolated groups or individuals may suffer from the common cold and if in these instances infection plays any role it must be assumed that some other factor made possible the attack by the infective agent. Some have asserted that explorers into arctic and antarctic regions are immune to colds, yet report was made by radio of an outbreak among Byrd's associates at Little America after isolation of about a year. This outbreak was attributed to opening a box of clothing. Also, Ellsworth was reported to be suffering from a cold when he and his pilot were rescued after a period of nearly two months removed from all contact with the outside world. There may be several factors to explain the relative freedom from colds among people in the arctic regions, explorers who make such journeys are in good physical

condition, including their reactions against cooling, they make elaborate preparations to protect themselves from the cold, they escape from some of the hazards of improper heating and ventilation of our modern homes, and their habits in eating and of drinking spiritous liquors are probably more rational than our own

TREATMENT

It is of interest to review the methods of treatment of the common cold. The prophylactic use of respiratory vaccines has already been mentioned, and it may be assumed that there is nothing specific in their action. In the treatment of the acute attack, several measures are of value. These may be grouped under two general heads: first, those measures which constrict the mucous membranes of the nose and permit the passage of air over them, second, those which open the peripheral vessels. In the first category will be found the shrinking solutions and applications, in the second, a warm room and warm bed, a hot bath, the mustard foot-bath, hot drinks, alcohol (given to the state of diplopia), acetylsalicylic acid, quinine, powder of ipecac and opium, papaverine and many another drug. Our chief concern in treatment is with the complications that result from the obstruction of the sinuses and the irritation of the lower respiratory passages. That the etiology of pneumonia is related to the effects of overcooling is indicated from the experimental studies of Robertson, who was able to reproduce the disease in animals only after the use of a drug (morphine) that caused a great reduction in the temperature of the body.

I am not in a position to state categorically that the common cold is due to a failure to make prompt adjustment to sudden changes in the temperature of our environment. However, there is evidence based on common experience and common sense that this is true. The general symptoms are those of constriction of the peripheral vessels. The local symptoms are related to disturbances of the erectile tissue of the nose, and the local reactions are nonspecific in character. If a filtrable virus is capable of causing rhinitis, it should not be concluded that it is necessarily the cause of the frequently recurrent attacks of the common cold. The absence of a lasting immunity would make the common cold unique among diseases known to be due to a filtrable virus.

I suspect that too much attention has been given to the minute living things in our environment, and too little study made of other elements of our environment which we must combat in order to live. It is as reasonable to suppose that changes in weather with universal exposure to unfavorable atmospheric conditions would cause an almost simultaneous outbreak of symptoms due to faulty adjustment to them. Chills and frozen fingers are not deemed contagious because an outbreak follows the onset of cold weather. Clouds of war gas and the menacing dust storm do not affect all persons equally and simultaneously. The same rules should be applied in considering the etiology of the common cold.

We are continuing our studies on the physiologic mechanism which I have discussed. We hope to be able to determine the interrelationships. Subjects known to be susceptible to the common cold will be exposed to environmental changes which may be expected to reproduce general and local symptoms characteristic of the common cold.

Since it is apparent that no rational means are available to prevent or treat the common cold on the basis of the hypothesis of infectious origin isn't it timely to go back to fundamentals and start anew?

THE VALUE OF PSYCHOANALYSIS AS A THERAPEUTIC PROCEDURE

HAROLD THOMAS HYMAN, MD
NEW YORK

Exponents of specialized therapeutic procedures must recognize certain definite obligations to their medical colleagues. These obligations include (a) controlled reports of clinical results, (b) discussions of failures and limitations, (c) the gratuitous training of younger practitioners, and (d) the application of the special technic for medical indications, irrespective of economic factors.

These comments are pertinent to the present attempt to evaluate psychoanalysis as a therapeutic procedure.

The literature of psychoanalysis, opulent in its imagery and broad vistas of potentialities, offers little tangible clinical information. There have appeared an abundance of abstract discussions of life and death, war and peace, politics and criminology, art and letters, education and pedagogy, love and hate, wit and humor, the conscious and the subconscious. But analyses of individual case histories, reports of failures, confessions of limitations, end results after a lapse of a reasonable span of time, allowances for the spontaneous course of disease (as in the manic-depressive psychoses), considerations of external factors such as arise in the life circumstances of any individual, attempts to adjudge the value of the results in terms of the time and money consumed—all these are conspicuously absent from the writings of men and women whose life work is devoted to the study and teachings of integrated cerebration. In a recent compilation of the literature by Dunbar,¹ containing 432 pages of print and 2,251 selected references, eleven pages are devoted to therapeutic considerations, without a single word relative to indications, contraindications, results or cost of therapy.

The Psychoanalytic Society has sharply limited its membership by adopting most rigorous professional standards. This has correctly made for responsibility and high quality of service in a field where charlatanism is rife. The limitation in the number of analysts has other aspects, however, for it has set up an economic structure for psychoanalysis which has given rise to great distrust. The first economic barrier is established for the young men in training. The Psychoanalytic Society demands a didactic analysis before election to membership. In violation of the hippocratic oath, these didactic analyses are not done gratuitously. Medical students and young practitioners of medicine are notoriously penurious and, until the economic barrier is broken down, many competent and serious students will be unable to meet the qualifications necessary for entrance into the Psychoanalytic Society. Money becomes a factor far too important in the training of these specialists. The limitation in number also serves to increase the premium which the accepted psychoanalysts place on their own services. Hence, in actual practice, the economic factor plays the greatest role in the selection of patients. Lawrence Kubie,² one of the wisest and sanest of the psychoanalytic school, has honestly and courageously, discussed these problems.

Read before the combined meeting of the New York Neurological Society and the Section of Neurology and Psychiatry of the New York Academy of Medicine, May 12 1936.

1 Dunbar, H. F. *Emotions and Bodily Changes (A Survey of Literature on Psychosomatic Interrelationships 1910-1933)*. Columbia University Press 1935.

2 Kubie, L. S. *Practical Aspects of Psychoanalysis*. New York, W. W. Norton & Co. Inc. 1936.

He estimates that the average fee for psychoanalysis in New York City is less than \$10 per hour. It is my experience that this figure represents a fair average. At 250 to 270 sessions a year the annual cost averages from \$2,500 to \$3,000. As an analysis is rarely terminated sooner than in eighteen months and in my experience more nearly two years, the total fee for the analysis may be estimated at an average of between \$5,000 and \$6,000. This would seem to limit sharply the availability of a therapeutic procedure. The rigidity of the economic arrangements demanded by many psychoanalysts results in further sacrifice on the part of the patient. At times the fee is requested in advance. No change in the analytic hour is tolerated. Payment is demanded for canceled time. Courtesies to fellow practitioners are waived. Patients usually report that the first interview with the analyst is taken up with the matter of finance. The acceptance of the patient by the analyst is often dependent on the size of the fee which the patient can pay in proportion to the premium which the psychoanalyst places on his free time.

The explanations which the analysts offer for their economic standards seem to be sheer rationalization. They aver that cooperation is not complete unless the patient makes a significant economic sacrifice. That this excuse has little justification in fact is illustrated by the experience of one reputable analyst of my acquaintance who has successfully handled five patients who paid him no significant fee. The psychoanalysts state further as explanation for their economic demand that diminished income affects adversely the analyst himself. Kubie states (page 190) that the very basis of the psychoanalyst's economic security may be seriously threatened and that he can make himself secure only by overworking, i.e. by taking on more patients than it is desirable for a man to carry. Where an analyst can obtain a fee of approximately \$2,500 to \$3,000 a year from each average paying patient, I cannot understand how a normally balanced person, such as an analyst must be to conduct his work, can possibly have his sense of security undermined by taking on one or two free patients or an occasional student for didactic analysis. If this condition prevails, either the analyst is rationalizing his greed or else his lack of sense of security in himself and his work borders on a true neurosis and hence renders him unfit for the continuation of his vocation.

The medical limitations to psychoanalytic therapy seem less well defined. Kubie states that psychoanalysis may be applied directly to the investigation of all the psychoneuroses and to their treatment, to the study of human discontent, i.e. the masked neuroses of the so-called normal, to the neurotic disturbances of childhood to the frank psychoses or insanity. He states that while a "fine intelligence is an asset," formal education matters little. Age is no factor—infants, children, adolescents and patients of advanced years may be acceptable and there have been efforts to study primitive savages and even the mental defective. This effectively covers most of human society and its ills, and fails to reveal any broad medical explanation for the rejection of patients on grounds other than fiscal.

The reticence of the psychoanalyst toward the referring physician is another sore point in analytic practice. It is only exceptionally, and then on repeated demand that I have been able to obtain any intelligent information concerning the progress and welfare of my patients. The transplanted European psychoanalyst

will not only furnish no information but actively resents any such request from the practitioner. The analytic rationalization of this behavior is based on their belief that reports may modify the free flow of material from the patient and may, by possible breach of confidence, give rise to embarrassing situations. Tacitly, it is insinuated that the average medical man cannot grasp psychoanalytic methodology. It is my belief that the isolation of psychoanalysis from the rest of medicine, discussed editorially in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*,³ is due in large part not to the hostility of the large body of physicians but to the reticence and arrogance of the analysts.

I am convinced that these rationalizations are a smoke screen and reflect either on the integrity or stability of the analyst. In any field, free discussion between the specialist and the referring physician is conducive to a cordial interrelationship, a warm feeling of confidence, and is invaluable in the education of both physicians. Such an exchange of information cannot be other than helpful to the patient. If the validity of the objections of the analyst toward sharing information with the referring physician while the analysis is in progress is granted, what can possibly prevent these reports from arriving after the analysis has been terminated?

In sharp contrast to the taciturnity of the analysts toward the practitioner is their volubility in discussing their work privately in the living room, over dinner tables, before meetings of mothers, social service workers, zealous pedagogues, criminologists, the literati, the artists, the intelligentsia, and other noncritical groups who possess neither the knowledge nor the authority to question the delmeator of the beguiling peregrinations of the human mind and soul. The parlor analyst vies with the parlor communist and the parlor endocrinologist—though in some instances the triad is miraculously concentrated in a single superman of superior imagination.

These comments concerning the practices of the analysts must not be interpreted as hostility for the achievements of psychoanalysis as a therapeutic measure. Kessel and I⁴ have previously stated that Freud and his followers have made "monumental contributions to the study of mental processes," that "the Freudian school offers the most intelligent approach toward the successful management of many psychiatric problems," and that "in a broader sense the newer teachings have widely influenced the methods of thinking and approach to many of the problems that are met in everyday practice." It is because we have expected so much of psychoanalysis that we have been so keenly disappointed in our results with individual patients, and so critical of the individual analyst.

In 1933 my late colleague Dr. Leo Kessel and I⁴ reported the therapeutic result in thirty-three patients who had been referred for treatment to accredited analysts. I now report on ten additional patients—a group of forty-three in all.

Fifteen patients suffered from profound psychiatric disease. Six of the patients were manic depressive and five were schizophrenic. There were two homosexual, one constitutional inferior, and one chronic alcoholic patient.

³ Eightieth Birthday of Sigmund Freud, editorial, *J. A. M. A.* 106: 1663 (May 9) 1936.
⁴ Kessel, Leo and Hyman, H. T. The Value of Psychoanalysis as a Therapeutic Procedure, *J. A. M. A.* 101: 1612-1615 (Nov. 18) 1933.
An Evaluation of Psychoanalysis, editorial, *ibid.* p. 1643.

Two of the patients committed suicide—one manic depressive, the other constitutionally inferior. The alcoholic patient, two of the manic depressive, and three of the schizophrenic have been committed to institutions.

Four others in this group may be counted as failures. Two of these individuals were manic depressive, one was schizophrenic and one homosexual. Since the termination of the analysis, one of the manic depressive in the latter group has become fairly equilibrated, but this is definitely through *vis medicatrix naturae*. The analysis had been terminated while the patient was in a severe depression some years before the present spontaneous recovery developed.

Another group of two patients is still under treatment. One of these is schizophrenic and has been in analysis for four of the past seven years. His analyst and members of his family believe that he is developing some insight into his psychosis and that he may in some way be benefited. The fugues in the manic-depressive patient may not be quite as marked in the periods either of elation or of depression. The analyst and the family are encouraged. The patient can see no definite improvement, and the course of the disease seems to me not unlike the course in many patients similarly afflicted who are receiving no specific therapy.

The last patient in this group of the seriously ill has made a brilliant recovery. This individual was homosexual. As the result of the analysis the patient is now married, has two children, and is successful professionally. This was indeed a life salvaged from the depths. It is my belief that this patient could have been rehabilitated in no other way and that the recovery is a signal triumph for psychoanalytic therapy.

In this small group of fifteen patients with grave psychiatric disorder there are twelve dismal failures, in two patients the results are still questionable and there is one specific therapeutic triumph. It is unfortunate that where the need is greatest the outlook is least bright. While, in its present state, psychoanalysis is uncovering interesting mechanisms in the profound psychiatric states, therapy for the most part is a forlorn hope and an expensive experiment. It seems justified only when families demand desperate remedies and because neither internists nor neurologists have anything to offer these patients that has even this minimum of promise.

A second group of twenty-eight patients suffered psychiatric disorders that were less crippling, less ominous and in many cases less susceptible of definite classification. Included in this group were patients with hysteria, anxiety states, anxiety hysteria, mild depression, phobias and obsessions, impotence and frigidity, behavior problems, hypochondriasis and at least one instance of psychosomatic abnormality.

Every practitioner of experience has daily contacts both in private practice and in the hospital with large numbers of patients who present any of a protean group of subjective symptoms without objective signs. Whatever terminology is used for these symptom complexes, the fact remains that these patients are unhappy and miserable—usually inefficient. The physical examination reveals no significant or pertinent abnormality. In most instances the intelligent practitioner who knows the life situation of his patient can obtain a satisfactory adjustment and often complete control of the symptomatology by reassurance, rest and vacations, recreational or vocational activity, symptomatic therapy, the

correction of familial and economic situations where possible, and the judicious use of sedation, physical therapy and hydrotherapy. The exhibition of ordinary human sympathy and understanding is the most valuable modality in the therapeutic armamentarium. In a certain number of instances, however, the symptomatology is obstinate, and this type of superficial therapy is ineffectual. Under these circumstances it has been our practice to refer the recalcitrant patient for analytic therapy. Hence the results obtained in this group by the analysts are the more notable.

This method of selection diminishes the number of individuals referred to the analysts, but it redounds the more to their credit when a therapeutic triumph is scored as the result of their specific therapy.

The analytic group will likely criticize this attitude and, as with the surgeons, they will ask for referred patients in the earlier phases of their difficulties. This, however, is wholly impractical, primarily for the economic reasons previously described and secondarily because reasonably satisfactory results may usually be obtained in the majority of instances by the simpler and less expensive methods that have been outlined.

Seventeen of the twenty-eight patients described were distinctly benefited by their analyses. In four instances the analytic cure could be applauded without reservation. This group included two patients with anxiety hysteria, one with an obsessional state and a phobia, and a fourth patient with psychosomatic disease. This last named individual, in addition to an anxiety state, had definite evidences of bronchial asthma and duodenal ulceration. Three years has elapsed since the termination of his therapy, and the splendid result that ensued psychically has also been apparent somatically. This is my one experience that is notable in the fascinating field where psyche and soma meet in related disturbances. This group, which would include certainly essential hypertension, exophthalmic goiter, probably gastroduodenal ulcer, certain types of colitis, and spastic constipation, might well prove a fertile field for the active cooperation of internist and analyst. Franz Alexander⁵ and his group in Chicago have studied similar disturbances, but their reports thus far have dealt with mechanisms rather than therapeutics.

Another thirteen patients were distinctly benefited by the analytic therapy. The results, however, in the latter subgroup were by no means as brilliant and clear cut as in the four patients previously described. These patients are better, they have benefited from their analyses, but in every instance the therapeutic result may possibly have been aided or brought about by alterations in the life situation. This group included three patients with behavior problems (lying, petty thievery, masturbation), one patient with a mild depression, five individuals with anxiety hysteria, one with claustrophobia, one with a characterological defect, two with masked neuroses, free from symptoms at the time of therapy and analyzed, for the most part, because their spouses had been successfully analyzed.

Eleven patients experienced no significant benefit from their analyses. These included one patient with impotence, one with frigidity, three who were hypochondriac, five individuals with anxiety neuroses, and one patient with an unclassifiable syndrome.

The previous statements concerning the limitations of psychoanalysis were confirmed anew. Besides the

5 Alexander Franz, Symposium on the Influence of Psychological Factors upon Gastrointestinal Disturbances, *Psychoanalytic Quarterly* 3, No. 4, October 1934.

economic limitation, age and intelligence were factors in prognosis. Before the middle twenties only the unusual individual can obtain any insight into the procedure. Beyond the age of 40 or 45 there seems to be little possibility of altering individuals. The successful patient must be the possessor of a plastic and a trained intelligence and, as a general rule, such patients have been recruited from the professions or the arts. The average man or woman is wholly unable to grasp or utilize this form of therapy. Those with profound and serious psychiatric disorders have neither the receptive attitude nor the moral fiber to profit from the information that is disclosed.

It would be unwise and unfair to attempt to summarize further the features of this presentation. The amount of the material is too small, though it has taken over fifteen years to collect these experiences. My own technical ignorance of the methodology of psychoanalysis is another vulnerable point in this discussion. It is, however, not too presumptuous to trust that the presentation of these tangible data may stir up sufficient debate and controversy to crystallize, for fellow practitioners, concrete indications and contraindications for a therapeutic procedure that offers great promise of fulfillment in the not too distant future.

940 Park Avenue.

HEART DISEASE AND PREGNANCY

JULIUS JENSEN, M.D.

ST. LOUIS

Cardiac clinics are now part of the standing equipment of most obstetric services. While a general trend toward a more successful management of these cases is apparent, there is disagreement on almost every detail of the problem. This is partly because of insufficient individual experience and partly because statistical methods have been neglected in the analysis of collected data. Therefore the present study was undertaken for the purpose of gathering sufficient data on controversial issues, and of treating these data statistically. For the purpose of detailed study nearly 1,000 case reports were collected from the literature and, to a small extent (fifty), from the records of the St. Louis Maternity Hospital.¹ More than 300 of these cases were fatal.

PUBLIC HEALTH ASPECTS

It is difficult to learn the prevalence of rheumatic heart disease among pregnant women. It probably varies according to climate, race and social stratum. The recorded incidence further depends on the care with which the patients have been examined and the accuracy with which functional conditions have been excluded. The high incidence of rheumatic heart disease found post mortem in New York and Boston may be due to the inclusion of cases that were clinically unimportant. On physical examination of samples of the young adult population the incidence has been reported to be about 2 per cent. This figure is probably too high, for it is estimated that about 2 per cent of the general population suffers from organic heart disease. But as the incidence increases greatly with age, it necessarily must lessen with youth.

An attempt has been made to estimate the incidence of rheumatic heart disease among white women of child-bearing age in the United States. Figures obtained from the census and the mortality tables for 1930 were corrected for all obvious errors as far as these could be estimated. The result was a probable death rate from rheumatic heart disease of 30 per hundred thousand white women of that age. If these deaths represent a death rate among these cardiac patients of 5 per cent, the incidence would be 0.6 per cent.

The recorded incidence of heart disease among more than 500,000 obstetric admissions to many different clinics both in this country and abroad was 0.9 per cent.

Heart disease is an important factor in 7 per cent of all deaths from puerperal causes. As there are about 14,000 deaths from puerperal causes a year in this country, probably about 1,000 of these are associated with heart disease. If these 1,000 fatal cases represent 5 per cent of the total incidence, this figure would be 20,000. Now, 20,000 is 0.91 per cent of 2,200,000 (the total number of births in 1930).

It thus seems probable that in this country the problem of heart disease concerns about 20,000 women each year or somewhat less than 1 per cent of all puerperal cases.

PHYSIOLOGIC EFFECTS OF PREGNANCY ON THE CARDIOVASCULAR SYSTEM

While everybody concedes that cardiac work is increased during pregnancy, there is little agreement as to how this increase is brought about. The most obvious explanation would be that the increase in body weight constitutes an added load on the heart. But cases have been recorded in which pregnant cardiac patients were relieved of symptoms of cardiac insufficiency when the fetus died, though it was retained in the uterus. The effects of mechanical pressure have failed to explain the case. Vital capacity has been considered, but while the detailed evidence is contradictory it seems certain that pregnancy does not cause any marked impairment of it. Neither do the metabolic demands of the ovum seem sufficient to explain the increase in cardiac work. There are no structural changes in the peripheral circulation during pregnancy sufficient to add materially to the heart's work. Possibly the increased tendency to contraction of capillary loops which accompanied pregnancy may be important. This applies both to the frequency and to the duration of these contractions and may be related to the slight increase in blood pressure which commonly accompanies pregnancy. The increase in the heart's work may be associated with the increased metabolic rate of pregnancy, though an increase in metabolism need not necessarily add to the work of the heart. There is an extensive belief and some evidence that the increase in metabolism is the result of thyroid hyperfunction. If that is so it may well be a cause of cardiac overwork. The circulating blood volume is definitely increased in pregnancy but its relation to the other factors is not yet clear.

Theoretically, at least, the circulation may take care of added metabolic demands without increasing the work of the heart, namely, by increasing oxygen utilization. The evidence as to whether this occurs during pregnancy is contradictory. An increase in peripheral resistance would be met by more powerful contractions and the blood pressure would go up. This occurs within normal limits in pregnancy. All direct and indirect evidence points to an increase in cardiac output during

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

¹ These were abstracted and analyzed by Dr. Birman.

pregnancy, that is, an increased minute volume. But it has not been decided whether this is brought about by increase in the heart rate or by increase in stroke volume or by a combination of the two. Pregnancy does not affect the blood velocity.

The increase in cardiac work during pregnancy results in cardiac hypertrophy to a degree which corresponds with the increase in body weight, that is, about 10 per cent. Probably there is also some dilatation of the heart, though this has not definitely been proved. This problem naturally is closely tied to that of stroke-volume. X-ray examination has so far been disappointing. The heart may undergo displacement and rotation which obscure both the shape and the measurements of the heart. Measurements generally show an increase in the shadow though to varying extent. By Kahlstorff's tridimensional method an enlargement of the cardiac volume has been found, amounting to some 10 per cent. In the electrocardiogram, pregnancy produced only unimportant changes in the electrical axis of the heart. During pregnancy, physical diagnosis is often made difficult by the presence of functional murmurs. Some of these seem to be intimately associated with the pregnant state, though the mechanism of their formation is obscure. The second pulmonic sound is also often accentuated in pregnancy.

The strain and other changes incident to pregnancy may sometimes produce signs and symptoms of advanced heart disease and failure, though there is no organic change in the heart. This so-called functional heart disease of pregnancy requires treatment which in most respects is similar to that of failure from organic heart disease.

HEART DISEASE AND PREGNANCY

The death rate among 2,400 pregnant cardiac patients admitted to various clinics was 5.8 per cent, or 50 per hundred thousand obstetric admissions. Among the 300 fatal cases previously mentioned, congestive failure was noted in about two thirds. It was the principal cause of death in one third. But, besides, the estimated death rate associated with childbirth from pneumonia, embolism, pulmonary infarction and sepsis is much increased among women with valvular disease of the heart. The estimated death rate from eclampsia and kidney disease does not seem to be affected by this complication. This is contrary to what was expected and to what has been stated elsewhere. Probably pulmonary complications and infections have a close causal relationship to congestive failure.

In most cases congestive failure occurs during pregnancy, but if the incidence is calculated not per phase of gestation but per time unit the greatest incidence of heart failure is during labor, thus the strain of labor is of real danger to the cardiac patient. The material did not justify the conclusion that the tendency to heart failure becomes greater as pregnancy advances. Many have stressed the importance of the occurrence of congestive failure early in pregnancy, though this relation may be coincidental.

The time of death in relation to the phase of gestation is more definite and therefore easier to determine. Especially in advanced pregnancy, women often deliver before they die; consequently the incidence of deaths expressed in relation to conception shows a steady increase throughout the period of gestation, but if it is expressed in relation to pregnancy it increases up to the seventh month and then decreases during the last months of pregnancy. It is not common for women

with heart disease to die undelivered after the seventh month of pregnancy. However, the greatest danger of death is during labor and during the first few hours after delivery. From then on the death rate rapidly declines except for a moderate increase during the second week of the puerperium. Then those die who developed pulmonary and other infections at the time of delivery.

The rate of decompensation and of death from heart disease increases rapidly with age. This also occurred in the present material of pregnant cardiac patients, but it could not be shown that the effect of increasing age on the death rate was altered by the state of pregnancy.

The prognosis is primarily determined by the state of the heart muscle, the greater the cardiac hypertrophy the gloomier the prospect, though some women with huge hearts go through childbirth without much trouble. The functional state of the cardiovascular system is important and the classification of the American Heart Association is finding increasing use in prognosis. Of the various valvular lesions, the combination of mitral and aortic lesions carries by far the highest death rate. The incidence of mitral stenosis was significantly higher among the fatal cases than among the women who survived, this may have been because mitral stenosis was a relatively serious lesion or because the diagnosis of mitral stenosis was missed clinically in many cases. The presence of auricular fibrillation in valvular heart disease increases greatly the chances of fatal outcome, perhaps because it here indicates that the disease is approaching the end of its course.

Isolated instances are recorded in which cardiac symptoms improved, but they generally get worse during pregnancy. It is frequently stated that pregnancy aggravates heart disease or that it shortens the life of the cardiac patient. In view of the fact that cardiac symptoms are not necessarily an expression of the pathologic organic changes in the heart, these two statements have not been proved. Actually they are difficult to test. Comparatively little is known of the life histories of cardiac patients, thus, controls are difficult to obtain. Simple follow-up studies are difficult to do because they may have to extend over many years. There is no evidence that the age at death is less among parous women, nor does it seem to be affected by increasing parity. There is no conclusive evidence that the period of survival after the first attack of rheumatic infection is shortened by pregnancy. The evil effects of pregnancy on heart disease seem chiefly to be that it may precipitate congestive failure when it is imminent and aggravate it when it is present.

A discussion of the treatment of this condition may be found elsewhere,² suffice it here to emphasize that proper care results in great saving of both maternal and fetal life.

3720 Washington Boulevard

ABSTRACT OF DISCUSSION

DR. L. A. CALKINS, Kansas City, Mo. The combination of heart disease and pregnancy offers a real problem. The diagnosis of heart disease in pregnant women is relatively easy. The diagnosis is missed in a number of patients, yet in general the diagnosis in the ordinary sense of the word is relatively easy, but that is not the whole story. The difficulty is as Dr. Jensen has pointed out that the diagnosis doesn't remain the same throughout the whole of the pregnancy. Because one has come to a conclusion at six weeks or three months or six months that the particular heart disease will or will not do well in

this particular pregnancy is not conclusive, because it may change. It is necessary continually to reexamine, rediscover and change one's concept and therefore the prognosis. Those who are interested have repeatedly pointed out that many patients who show relatively little in the early months of pregnancy—not enough indeed to make a diagnosis of heart disease of any kind—will by the end of seven and one-half or eight months show plenty of signs. The main question is how these patients can best be handled. I have been surprised to hear an internist well versed in heart diseases make the statement that if all patients with severe mitral disease could be delivered by cesarean section there would be no mortality. This statement, of course, is far from the truth. What should be done? Probably, as Dr. Jensen has pointed out, following the test laid down by the American Heart Association, the response to exercise will best indicate the course of action. Those responding poorly should probably be subjected to cesarean section after partial digitalization. Those responding well to exercise will probably withstand the rigors of labor comparatively well.

DR. RALPH LUKART, Omaha. I concur in the need of a subspecialty—obstetric cardiology. I wish to emphasize this point because of the tendency to minimize the dangers of heart disease in pregnancy. As Dr. Jensen stated, selected cases with simple mitral stenosis may carry on through pregnancy and labor without great danger. A diseased heart associated with pregnancy which tolerates the daily duties should withstand the burden of labor equally well. If the patient exhibits shortness of breath and other signs of heart failure before labor, the probabilities of her getting into difficulties are increased. These clinical symptoms should be of greatest prognostic value to the obstetrician. There is additional risk to the patient directly proportionate as the following complications are superimposed on a mitral stenosis: hypertrophy, aortic lesions, auricular fibrillation and, finally, endocarditis or pericarditis with friction rub or both. Patients in the latter three groups and those who are decompensated should never be permitted to become pregnant. When an obstetrician is confronted with any of these conditions he should realize that the pregnancy is secondary. A cardiologist should also be in attendance throughout the pregnancy and the first few weeks post partum. There is no pregnancy in which intelligent antepartum care is more needed. There must be proper management of rest and exercise, and of the diet with weight control, in order to minimize the danger of toxemia complicating the heart disease. The group of fatal pregnant heart cases reported by Dr. Jensen revealed that a high percentage of the deaths occurred during labor. These statistics emphasize the necessity of having the patient in the best possible condition to meet the ordeal of labor and of making the delivery as free from burden to the patient as possible. Each case must be individualized. Normal rapid delivery via the birth canal without intervention is best, but if this tends to create difficulties and undue exhaustion, low cesarean section with spinal or local anesthesia offers the best chance for mother and baby. Every possible need for stimulants in case of collapse at the time of delivery should be anticipated.

DR. JULIUS JENSEN, St. Louis. I wish to emphasize antepartum care. It is important not to guess at the problem. Each case should be studied in detail and the importance of each factor involved evaluated. A good illustration of the results which can be obtained by proper treatment is that obtained in the Boston Lying-in Hospital, where the death rate has fallen from 12 per cent some years ago to 3 per cent at the present time. The physical examination may give confusing results. Dr. Rickard some years ago selected cases of pregnant women with mitral stenosis to be demonstrated to a class of post-graduate students because they presented typical physical signs but when they were shown to the students the signs had changed so much that it was difficult to convince the class that mitral heart disease was present. Therefore, repeated physical examinations are necessary. In heart disease rapid delivery is, as a rule, not to be recommended. In the past it was customary to handle an emergency with rapid delivery and often by brutal methods, the results were almost uniformly disastrous. Conservative management that avoids any unnecessary strain on the part of the mother will lead to much better results.

SALMONELLA SUIPESTIFER BACTEREMIA

WITH PERICARDITIS, PNEUMONITIS AND PLEURAL EFFUSION (REPORT OF A CASE)

LESTER COHEN, M.D.

HAROLD FINK, M.D.

AND

IRVING GRAY, M.D.

BROOKLYN

The rarity of reports of *Salmonella suispestifer* infection in human beings and the bizarre clinical picture usually present in the sporadic case prompt this report. For the past two decades this organism has been known to be pathogenic for man. Until the World War the *Salmonella suispestifer* organism was known to be the cause of hog cholera. Since that time there has been increasing evidence of its definite relationship to human disease. The disease in human beings may express itself in either epidemic or sporadic form. The epidemic type of *Salmonella suispestifer* infection was always associated with food poisoning. The sporadic case associated with bacteremia has been reported only since 1919. We report another case of *Salmonella suispestifer* bacteremia with unusual clinical features.

LITERATURE

Epidemics of gastro-enteritis were reported from southern Europe and Asia Minor by MacAdam,¹ and in Serbia by Hirschfeld.² The cause of these epidemics was found to be a bacillus similar to that of typhoid and was named the paratyphoid C bacillus. This bacillus was identified in 1920 by TenBroeck,³ and by Andrewes and Neave,⁴ as a member of the *Salmonella suispestifer* family. In 1922 Krumwiede and his associates⁵ reported an epidemic of acute gastro-enteritis after the ingestion of contaminated tapioca pudding. The same year Stewart and Litterer⁶ reported an outbreak after the ingestion of raw milk. Proof that the paratyphoid C organism was truly *Salmonella suispestifer* was established by Savage and White⁷ in 1925. They studied a family in which the intake of contaminated cheese produced an acute gastro-enteritis. From their studies they believe that the organism was of low virulence and that under special circumstances it could produce human infection. Several instances of *Salmonella suispestifer* infection were reported by Cowern⁸ in 1926, among travelers in areas in which "intestinal grip" was prevalent. Contaminated ice cream was held to be the source of infection in the Offenbach epidemic in 1927. More than 100 persons were affected, as reported by Braun and Mündel.⁹

When the infection occurs in isolated instances, that is, the sporadic type, there may be either localized disease or a general bacteremia. A localized osteomyelitis due to *Salmonella suipestifer* involving the upper end of the humerus and the shoulder joint was reported by Gajzago and Göttsche¹⁰ in 1935. These authors mention the possibility of a preexisting infection of the blood stream. A comprehensive review of the bacteremias caused by *Salmonella suipestifer* infection was reported by Gouley and Israel¹¹ in 1934. It is with their permission that we publish table 1.

In each of these case reports the bacillus was found in pure culture in the blood, except for the case reported by Nabarro and White¹². In their case the organism was recovered from the fluid in a synovial sac. The case we are adding to this group of bacteremias is the first time an acute pericarditis has been reported complicating *Salmonella suipestifer* bacteremia. Approximately forty-eight hours after admission to the hospital the patient developed an effusion in the

Physical Examination.—The patient was well nourished, was acutely ill, with a moderate degree of cyanosis, and was breathing rapidly, with an expiratory grunt. The pertinent conditions observed were congestion of the pharynx, restriction of respiratory excursion of the chest and dullness at the right base, posteriorly, over which area a friction rub was heard. The heart action was rapid but otherwise showed no abnormalities and the abdominal examination was "negative." The spleen was not felt nor did it percuss enlarged. The blood pressure was 150 systolic, 100 diastolic.

Progress Notes.—First Week. A dusky cyanosis, rapid and shallow breathing, high fever and high pulse rate were all indicative of a critical illness. A to and fro friction rub was, for the first time, heard over the precordium on the third day. There were signs suggestive of fluid in the right pleural cavity and a pneumonitis and pleuritis over the right lower lobe. X-ray examination of the chest, at the bedside, showed signs suggestive of a pneumonitis involving both lower lobes, thickening of the right pleura and signs indicative of fluid in the right pleural cavity. The cardiac shadow was somewhat larger than usual (correct measurements could not be determined because a 6 foot film was not taken). On the fourth day a to and fro friction rub over the precordium was distinctly audible. Within

pericardium. Furthermore, she had a pneumonitis of the left lower lobe and a right-sided pleuritis with pleural effusion. Involvement of the pulmonary parenchyma and pleural effusion have been noted in previous instances. Gouley and Israel¹¹ report the occurrence of acute endocarditis in their patient. This is the first time that pericarditis has been encountered in *Salmonella suipestifer* bacteremia.

REPORT OF CASE

History.—E. D., a white woman, aged 36, admitted to the medical service, April 27, 1935, complained chiefly of pain in the right side of the chest and difficulty in breathing, of three days' duration. The family and past histories were essentially negative except for the fact that she had had three spontaneous abortions. Her present illness started with a sore throat two weeks prior to admission. Seventy-two hours before hospitalization the patient developed a severe pain in the right side of the chest, dry cough and profuse perspiration. She was sent to the hospital. There was no history of any gastro-intestinal disturbances nor was any member of the family ill either with an infection of the upper respiratory tract or with abdominal symptoms. On admission the temperature was 103 F, pulse 112 and respiration 36.

forty-eight hours there was increase in the precordial dullness suggestive of fluid in the pericardial sac. The pericardial rub was localized to the third and fourth intercostal spaces. The temperature ranged between 103 and 105 F. At the end of the first week there were definite signs of fluid in the right pleural cavity. Fifty cubic centimeters of clear yellow fluid was withdrawn from the right pleural cavity (positive Rivalta test). No organisms were found on direct smear. A culture was sterile.

Second Week. Pyrexia continued, ranging between 103 and 104 F. There was an increase in the cardiac dullness, both to the right and to the left. The friction rub was less audible and the heart sounds were more distant. X-ray examination confirmed the diagnosis of a pericardial effusion. Signs of pneumonitis were less marked, there was a moderate amount of fluid in the right pleural cavity. The patient's condition was still critical. The temperature, pulse and respiration remained elevated. A pericardial tap was done and 10 cc. of hemorrhagic fluid was obtained. Because of the character of the fluid no attempt was made to remove more than 10 cc. Several blood cultures taken to date were reported as sterile.

Third and Fourth Week. A blood culture taken forty-eight hours after admission was reported as positive (one colony of *Salmonella suipestifer* per cubic centimeter of blood). The clinical picture remained unchanged. The patient was critically ill with an acute pericarditis and pericardial effusion and also with an effusion in the right pleural cavity. The right pleural cavity was aspirated and 135 cc. of straw colored fluid was withdrawn. Ten days later 200 cc. of straw colored fluid was obtained on aspiration. The bronchopneumonic process in both

lower lobes and the pleuritis of the left side of the chest appeared to be subsiding. Pyrexia continued. Signs of pericarditis with effusion continued. Electrocardiographic studies showed first stage heart block and a deep Q.

Fifth and Sixth Weeks. A blood culture taken on the ninth day after admission to the hospital was now reported positive. This was the second positive blood culture and showed the same organism as reported in the first blood culture. There were two colonies of *Salmonella suipestifer* per cubic centimeter of blood. The signs of pericardial and pleural effusion appeared to be diminishing. The pyrexia likewise was less marked, the temperature ranging at this time from 99 to 100 F. Clinically the patient was improving.

Seventh and Eighth Weeks. The temperature at the end of the eighth week was slightly elevated, ranging between 100.5 and 102 F. The urine, which previously showed no abnormalities, now was found to contain a few red blood cells and a few pus cells. These signs were present for approximately one week and gradually abated. Cystoscopic examination showed no abnormalities. Culture of the urine failed to reveal *Salmonella suipestifer*. X-ray examination of the chest corroborated the physical examination that the size of the heart had returned to normal and that the fluid in the right pleural cavity was completely absorbed. There was some thickening of the pleura over the right lower lobe.

Ninth and Tenth Weeks. The temperature, pulse and respiration were normal. The patient's condition was much improved. There was a rapid convalescence back to normal health. Seventy-four days after admission to the hospital the patient was discharged as recovered with a diagnosis of *Salmonella suipestifer* bacteremia with pericarditis, pneumonitis and pleuritis.

Laboratory Examinations.—With the exception of the blood study on admission, which showed a white blood count of 16,200 with 90 per cent polymorphonuclears, three subsequent blood examinations revealed a persistent leukopenia (5,200 with 82 per cent polymorphonuclears, 6,800 with 80 per cent polymorphonuclears, 7,850 with 64 per cent polymorphonuclears). The leukopenia was consistent with the observations of Gouley and Israel¹¹ who remarked on a similar condition in their patient. The Widal reaction was negative. The pleural fluid showed a positive Rivotla test (specific gravity 1.024). The microscopic examination of the fluid showed an occasional lymphocyte. The pericardial fluid was grossly bloody and clotted soon after removal. A guinea-pig inoculated with some of this fluid died five days later of extraneous causes.

Bacteriologic Examinations.—Blood cultures on two occasions showed gram-negative motile bacilli. These gave an agglutination reaction with typhoid and paratyphoid serums. Agglutination took place in the highest titer with paratyphoid B serum.

The sugar reactions of this organism are given in table 2. The organism was agglutinated by the patient's serum in a dilution of 1:640. Control bloods gave no agglutination.

TABLE 2—Sugar Reactions of Organism

| Sugar | Reaction |
|------------------------|-----------------------------|
| Lactose | No fermentation |
| Dextrose | Acid and gas |
| Saccharose | No fermentation |
| Mannite | Acid and gas |
| Maltose | Acid and gas |
| Russell's double sugar | Slant acid Butt alkaline |

Gelatin was not liquefied. A hanging drop showed three plus motility. The Department of Health of the City of New York corroborated these sugar reactions and serologically identified the organism as *Salmonella suipestifer*.

COMMENT

The symptomatology of the infection due to *Salmonella suipestifer* bacteremia has been divided into three groups:¹¹ gastro-enteric, pulmonic and septic. Among the twenty-one cases of *Salmonella suipestifer* bacteremia in adults heretofore reported the predominant signs and symptoms were referable to the gastro-intestinal tract (sixteen cases). In the remain-

ing five the symptomatology was confined largely to the lungs and pleura. True lobar pneumonia due to *Salmonella suipestifer* was reported by Bullova,¹³ and was verified by blood culture, sputum and postmortem examinations. The endocarditis¹¹ developed in a child, aged 4 years, who was acutely ill for approximately two weeks with *Salmonella suipestifer* bacteremia. In a case reported by Andrewes and Neave,⁴ pyuria was present, although the predominant symp-

The weekly temperature curve. A first blood culture (reported as positive three weeks later) B, pneumonitis C, pericarditis (fourth day) D pleural effusion (right side of chest at end of first week) E second blood culture (reported as positive for weeks later) F pericardial tap G hematuria plus pyuria

toms were referable to the lungs. Their patient likewise had a pleural effusion. In one of the patients with *Salmonella suipestifer* bacteremia observed by Kuttner and Zepp¹⁴ a cystitis developed. Culture of the urine obtained on cystoscopy in our patient failed to show the organism.

Unlike the cases previously reported which usually showed a low white blood cell count in our patient during the first three days there was a moderate leukocytosis (14,000). Subsequently, despite the pyrexia, there was a leukopenia (between 6,000 and 8,000) and a practically normal differential count. Leukopenia is to be expected in the bacteremia caused by *Salmonella suipestifer*, since this organism is a member of the typhoid family. As Gouley and Israel¹¹ state:

Agglutination reactions with *suipestifer* should be borne in mind in any case of apparent typhoid or paratyphoid fever with a negative Widal reaction, but it must also be remembered that positive agglutination in high titer may not develop for many months. Moreover, a cross-agglutination between the patient's serum and paratyphoid bacillus B often occurs during the acute stage of infection caused by *suipestifer* a fact that obscured the true identity of the latter organism until the characteristic carbohydrate fermentations were discovered and standardized. The positive blood culture and the carbohydrate reactions, therefore, lead to an accurate diagnosis, it is obvious that the matter of recognition of *Salmonella suipestifer* requires a competent bacteriologist.

SUMMARY

This is the first case to be reported of sporadic *Salmonella suipestifer* bacteremia with acute pericarditis and pericardial effusion. The patient had a pneumonitis and pleural effusion also. Recovery was uneventful and not associated with any sequela.

THE AUTONOMIC NERVOUS SYSTEM IN RELATION TO OTOLARYNGOLOGY

ALBERT KUNTZ M.D.

ST. LOUIS

The autonomic innervation of the mucous membranes and involuntary musculature of the upper respiratory tract the paranasal sinuses, the middle ear and the auditory tube includes both sympathetic and parasympathetic nerves. The sympathetic nerves are derived mainly from the superior cervical sympathetic ganglion, the parasympathetic nerves arise mainly in the sphenopalatine ganglion and the intrinsic ganglions of the pharynx and larynx. The preganglionic fibers that connect the superior cervical sympathetic ganglion with the central nervous system are components of the upper thoracic nerves. The sphenopalatine ganglion is connected with the brain stem through preganglionic components of the facial nerve, the intrinsic ganglions of the pharynx and larynx are connected through preganglionic components of the vagus nerve. The sympathetic fibers that reach the mucous membranes of the nose, the paranasal sinuses and the nasopharynx extend cephalad in the internal carotid plexus, join the sphenopalatine ganglion by way of the greater superficial petrosal nerve and the nerve of the pterygoid canal, and reach their peripheral distribution through nerves that arise from the sphenopalatine ganglion. Of those which supply the inferior portion of the pharynx, some join the pharyngeal plexus through separate sympathetic rami, others become incorporated in the pharyngeal branches of the vagus before reaching the pharynx and join the pharyngeal plexus with these nerves. The sympathetic fibers that supply the larynx reach it mainly through the pharyngeal plexus, but in part also through the laryngeal vagus branches. The parasympathetic fibers that supply the mucous membranes of the nose, the paranasal sinuses and the upper parts of the pharynx traverse the nasal, palatine and pharyngeal rami which arise directly from the sphenopalatine ganglion. Those which supply the inferior portion of the pharynx and larynx are derived mainly from the intrinsic ganglions.

The afferent or sensory, innervation of the mucous membranes of the nose, paranasal sinuses and nasopharynx includes mainly components of the trigeminal nerve. Afferent components of both the vagus and the upper thoracic spinal nerves also reach the area of distribution of the trigeminal by way of the plexuses on the common, internal and external carotid arteries.¹ Some of these terminate in the mucous membranes in question. The afferent innervation of the inferior portion of the pharynx includes components of both the glossopharyngeal and the vagus nerves, that of the larynx includes probably exclusively vagus components.

FUNCTIONAL REGULATION OF MUCOUS MEMBRANES

The functional state of the mucous membranes, including their secretory and ciliary activity, is regulated and controlled through the autonomic nerves and is intimately related to the functional state of the peripheral blood vessels. While the mucous membranes

are hyperemic, i. e., during intervals of capillary dilatation, the number of leukocytes in the blood in these vessels is markedly increased. The capillaries further more exhibit increased endothelial permeability, consequently, leukocytes escape from the vessels into the tissues and many of them reach the surface of the epithelium. While the mucous membranes are ischemic, i. e., during intervals of capillary constriction, the number of leukocytes in the blood is markedly diminished. Endothelial permeability also is decreased, consequently, few leukocytes escape from the vessels.

The general splanchnoperipheral interactions of the body are such that the autonomic status of the abdominal and pelvic organs is opposed to that of the extraperitoneal organs and tissues. By virtue of this relationship, the autonomic status of the buccal and respiratory mucous membranes corresponds to that of the skin. Under physiologic conditions, particularly during bodily rest, the blood supply of the abdominal and pelvic organs is more abundant than that of the extraperitoneal structures. During intervals of relatively high external temperature or muscular activity, the autonomic status is reversed, consequently, the splanchnoperipheral blood volume ratio is shifted in favor of the extraperitoneal structures. If the body is exposed to low temperatures, particularly in the absence of muscular activity, the skin becomes relatively ischemic, owing to peripheral vasoconstriction. Since the autonomic orientation of the buccal and respiratory mucous membranes corresponds to that of the skin, they also become ischemic.

Under ordinary physiologic conditions, the local resistance of the respiratory mucous membranes is sufficient to prevent infection, although infective organisms are always present. Prolonged ischemia of the mucous membranes reduces the local resistance and favors infection. This is well illustrated by infections of the upper respiratory tract following exposure to low temperature or drafts. That the reduction in the local resistance of the mucous membranes is not a direct effect of exposure to low temperature is evidenced by the fact that if, during such exposure, peripheral vasoconstriction is prevented by muscular activity, infection does not take place. Not infrequently respiratory infections are contracted in the absence of any appreciable lowering of the temperature of the mucous membranes beyond that which is attributable to the local ischemia.

The defensive inflammatory reactions of the mucous membranes elicited by the toxic substances resulting from infections depend on the autonomic status of the tissues as such. Since these reactions involve local vasodilatation, they are inhibited during the period of the general reaction to the infection, since that period is characterized by peripheral vasoconstriction. The tissues in the infected area later become oppositely oriented, local vasodilatation with leukocytosis takes place, tissue metabolism is accelerated, and the local resistance is greatly increased. The inflammatory reaction, therefore, differs only in degree from the normal physiologic response.

ALLERGY

The relatively high incidence of allergy in patients with sinusitis and lesions of the nasal mucosa strongly suggests the existence of certain common etiologic factors. That the autonomic nerves are at fault in allergic disorders is indicated by the sudden appearance of their manifestations, e. g. the localized collection of liquid as in angioneurotic edema or sudden bronchospasm as in asthma and the equally sudden disappearance of

From the St. Louis University School of Medicine.
Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14 1936.

symptoms in response to agents such as epinephrine, which act primarily on the autonomic nerves. The comparative absence of fever in allergic states also indicates metabolic changes that differ from those commonly associated with infections. The breaking down of the absorbed protein of the individual is disturbed and histamine-like substances are liberated, particularly in the skin and mucous membranes. These substances probably represent the immediate causes of the allergic reactions.

In cases of allergic rhinitis, the water content of the nasal secretion is increased and the calcium content is diminished. The mucous membranes are hyperemic, indicating vasodilatation with increased capillary permeability, accelerated tissue activity and hydration. This condition conforms to the "parasympathetic status" as defined by Petersen and Levinson.² The converse condition, namely, vasoconstriction with decreased capillary permeability, results in reduced cellular activity, decreased permeability of the cell membranes, hydration of the protoplasm, and calcium concentration. This condition conforms to the "sympathetic status" as defined by Petersen and Levinson.

The chemical alterations demonstrable in the nasal secretions in allergic states do not represent merely local changes. The reduction in the calcium content of the nasal secretion probably is an expression of a shift in the acid-base balance of the body fluids toward alkalinity. The acid-base balance, which is closely associated with the autonomic balance, therefore, must be regarded as an important factor in the etiology of allergy. This also is indicated by the fact that clinical improvement, in cases of allergic rhinitis, is accompanied by an increase in the calcium content of the secretion, indicating a shift in the acid-base balance toward the normal and, consequently, a shift in the autonomic balance in the same direction. In view of these considerations, therapeutic measures designed to restore the acid-base balance and consequently the autonomic balance seem to be indicated in allergic cases and in various other conditions in which the functional activity of the respiratory mucous membranes is disturbed.

REFLEX REGULATION OF THE CAVERNOUS TISSUE

The cavernous, or erectile, tissue in the nasal mucosa does not always conform to the vascular state of the adjacent mucous membrane, although its blood vessels and those of the adjacent mucous membrane are innervated by the same nerves. Various investigators, particularly Sternberg,³ have called attention to the facts that engorgement of the cavernous tissue frequently takes place while the mucous membrane is relatively ischemic and that not infrequently it contracts while the mucous membrane is markedly hyperemic. Application to the nasal mucosa of certain pharmacologic agents which regularly cause hyperemia of the mucous membrane results in contraction of the cavernous tissue, consequently it has been assumed that the vessels of the cavernous tissue react to nerve stimulation in a manner differing from that of the vessels of the adjacent mucous membrane.

According to the early studies of Zuckerkindl,⁴ the capillary bed in the cavernous tissue is interposed

between veins, whereas the capillary bed in the other parts of the nasal mucosa is interposed between arteries and veins. The blood that flows through the cavernous bodies is derived from the subepithelial capillary plexus and the more superficial portion of the periglandular plexus. In view of this arrangement, it seems not improbable that reflex stimulation which elicits vasoconstriction in the nasal mucosa might prevent emptying of the capillary bed in the cavernous tissue by contraction of the veins into which it drains. Reflex stimulation which elicits vasodilatation in the nasal mucosa, on the contrary, probably results in contraction of the cavernous tissue because the outflow of the blood is facilitated by the dilatation of the veins.

REFERRED PAINS

Pains associated with lesions in the nasal, paranasal and mastoid areas but localized in other cephalic areas and in the neck, upper thorax and upper extremities are not uncommon. These pains exhibit the characteristic features of referred pains and in many instances are accompanied by other referred phenomena. According to Head's theory, which is supported by extensive data and probably is applicable in all cases of referred pain, the areas in which such pains are localized always fall within segments of the body that are supplied by nerves which also supply afferent fibers to the site of the lesion.

Pains associated with lesions of the nasal and paranasal mucous membranes which are localized within the area of distribution of the trigeminal nerve, but not at the site of the lesion, obviously conform to Head's theory and consequently may be regarded as referred pains. Pain in the temporal region associated with a lesion of the sphenoid sinus and pain in the frontal region associated with a lesion of the maxillary sinus obviously can be explained most satisfactorily on this basis. Pain in the occipital region associated with a lesion of the nasal mucosa also conforms to Head's theory of the localization of referred pain, since the trigeminospinal tract descends to the level of the upper cervical nerves through which the occipital region receives its afferent innervation. The demonstration of afferent components of the upper thoracic nerves in the area of sensory distribution of the trigeminal nerve, previously referred to, furthermore affords the anatomic basis for the interpretation of pains in the lower cervical and upper thoracic segments and the upper extremity associated with lesions in the nasal, paranasal and mastoid areas as referred pains in conformity with Head's theory of localization.

The autonomic nerves undoubtedly play a role in the production of referred pains but not as conduction pathways for pain impulses. The assumption that reflex responses elicited by the stimulation of afferent fibers at the site of the lesion or adjacent to it, through the sympathetic nerves in the area in which the referred pain is localized, results in stimulation of pain receptors in that area is supported both by clinical and by experimental data. One of the common reflex responses in an area in which a referred pain is localized is vasoconstriction. Vasoconstriction, as is well known, not infrequently gives rise to pain, but there is no general agreement regarding the stimulating agent that acts on the pain receptors. Certain investigators, particularly Lewis, Pickering and Rothschild,⁵ Popper⁶ and Schret-

zenmayr,⁷ have advanced data which seem to support the view that the stimulating agent giving rise to pain associated with ischemia is essentially chemical. Waterston⁸ has advanced certain data in support of the assumption that peripheral pain due to local injury also is caused by a chemical agent and that this substance is identical with that which is liberated by viscerocutaneous reflexes. According to Kissin,⁹ anoxemia is an important factor in the production of pain. Within certain limits the severity of the pain and the rapidity of its onset, in exercising muscle, varies with the degree of anoxemia. The stimulating agent seems to be accumulated products of muscular metabolism, the disposal of which requires oxygen. According to Katz, Lindner and Landt,¹⁰ the substance that stimulates the pain receptors is acid in nature and diffuses into the blood. It also is nonvolatile, since it is active after passing through the lungs.

The mechanisms through which the reflex phenomena associated with referred pains are brought about consist essentially of visceral or somatic afferent neurons through which afferent impulses are conducted from the site of the lesion into the cerebrospinal axis, visceral efferent neurons located in the intermediolateral cell column which conduct the impulses to the sympathetic trunk and sympathetic neurons located in the corresponding ganglions of the sympathetic trunk, through which efferent impulses are conducted to the smooth muscle in the area in which the referred pain is localized. The impulses arising in the pain receptors in this area owing to the stimulating effect of the reflex responses are conducted toward the center by the ordinary pain-conducting fibers. The components of referred pain that are due to the reflex phenomena in the area of reference, consequently, may be regarded as the direct result of pain impulses arising in this area.

According to the conception of the mechanisms of referred pain previously outlined the components of referred pains of nasal and paranasal origin localized within the area of distribution of the trigeminal nerve which are due to reflexes elicited through the sympathetic nerves may be explained as follows. Impulses arising at the site of the lesion are conducted into the brain stem through the corresponding division of the trigeminal nerve. The trigeminal fibers in question effect reflex connections with visceral efferent neurons in the upper thoracic segments of the spinal cord. The axons of these neurons join the sympathetic trunk and ascend to the superior cervical ganglion, where they effect synaptic connections with sympathetic neurons whose axons extend into the area in which the referred pain is localized. The impulses generated in the pain receptors in this area are conducted into the brain stem through the pain conducting trigeminal fibers with which it is supplied.

The mechanisms involved in the autonomic components of referred pains of nasal origin which are localized in the occipital region are essentially similar to those outlined, except with respect to the sympathetic and afferent nerve supply to the area in which the pain is localized. The sympathetic fibers in question join the upper thoracic nerves through their gray rami and reach

the occipital region through the occipital nerves. The pain impulses generated in this area are conducted into the spinal cord through the occipital and upper cervical nerves, and upward through the lateral spinothalamic tract of the opposite side.

The autonomic components of referred pains localized in the lower cervical and upper thoracic segments and the upper extremity which are due to lesions in the nasal, paranasal or mastoid areas can be explained most satisfactorily as follows. Impulses arising at the site of the lesion reach the upper thoracic segments of the spinal cord through afferent spinal nerve components which traverse the plexuses on the common and internal carotid arteries. These fibers effect connections with visceral efferent neurons in the spinal cord, through which the impulses are conducted into the corresponding ganglions of the sympathetic trunk, where they are transmitted to sympathetic neurons, through which they are conducted toward the periphery. The impulses that arise in the peripheral pain receptors are conducted into the spinal cord through afferent components of the corresponding spinal nerves and upward in the lateral spinothalamic tract on the contralateral side.

1402 South Grand Boulevard

ABSTRACT OF DISCUSSION

DR. LEO STONE Topeka Kan. The autonomic nervous system, in both its outflows, is subject to central control, probably in the diencephalon, and this autonomic center has direct connection with the cerebral cortex. It has been shown in recent years that there is probably autonomic representation in the cerebral cortex itself. The cerebral cortex may be assumed to be the principal site of mental processes, and thus, thought may be brought into relation with the autonomic nervous system as with allergy. That people of allergic diathesis are often intensely neurotic has long been recognized. Remarkable fluctuations in allergic illnesses on an emotional basis have been observed. However, only a few bold physicians have assumed that allergic manifestations, whether in the nose or in the bronchial tree, are predominantly neurotic. To make such an assumption is no startling when one realizes how closely many instances of allergy correspond to the conditioned reflex mechanism. Such a relationship is most clear in adult acquired sensitizations, especially in the marital and occupational spheres. Certainly it is not rash to assume that a whole constellation of events and circumstances may in some instances be represented by a precise physicochemical stimulus, even though one feels that such an interpretation is not exclusively explanatory. One cannot avoid the constitutional and familial factors which are so conspicuous among allergic subjects. Nor would any one wish to deprecate the importance and awful biologic directness of the anaphylactic phenomenon even though one may question how large and how fixed a part this plays in the everyday case of clinical human allergy. It would be wasteful and fanciful to wander far into the psychic life of a relatively well adjusted individual whose asthma or allergic rhinitis and perhaps coincident sinusitis can be relieved by the simple exclusion of one or more foods from his diet, by direct quantitative methods of desensitization, or by mechanical treatment of the paranasal sinuses themselves. It may however prove useful to remember that the cortical symbolic level may enter into what are apparently autonomous vasomotor reactions. An occasional resistant patient may merit careful investigation of the cortical aspects of his autonomic disorder, as in hysteria and such investigation may at times have a remarkable therapeutic effect.

DR. GORDON F. HARKNESS Davenport, Iowa. One must epitomize and keep in mind a few fundamentals. The autonomic nervous system of profound effect but not essential to life is essentially an efferent system, supplying a double innervation to viscera, smooth muscles and glands through its two subdivisions, namely the sympathetic and the parasympathetic. Many of the nerve tracts essential to their functioning are not known. The essential anatomic differences between the two subdivisions

lies in the fact that in the sympathetic system the preganglionic components join the sympathetic trunk close to the vertebral column, while in the parasympathetic system the preganglionic components go directly to a peripheral ganglion. The superior cervical ganglion which supplies the sympathetic innervation within the head differs in that it receives no afferent fibers although its preganglionic fibers may come from as low as the seventh dorsal segment. The cephalic preganglionic fibers of the parasympathetics connect the ganglions with the brain stem and form components of the third seventh ninth tenth and eleventh cranial nerves. Since part of our knowledge is based on hypotheses, it is now proposed by some that a further subdivision be made in each system into motor and inhibitory groups. Surgical therapy as applied to the sympathetic system is an attempt to relieve symptoms by interrupting afferent and efferent stimuli from or to an organ or area. Surgery of the superior cervical ganglion supplies the cephalic sympathetic innervation. It should be remembered that it has branches that go to the esophagus the phrenic the superior laryngeal and the twelfth nerves and that it originates the superior cardiac nerve. What pharmacology may discover in the future may offer more in scientific application than the present-day conclusions from anatomic studies. I can only reiterate a conclusion stated three years ago relative to the autonomic nervous system and otolaryngology. 'The complexities of the chemistry of body metabolism obscure and make difficult a definite association of symptomatology with the autonomic nervous system. In its present development clinical application is disappointing but seems to possess future possibilities.

DR HARRIS H. VAIL Cincinnati. The present status of the autonomic nervous system in otolaryngology is still very much confused. Surgery on the cranial autonomic and sympathetic nervous systems is in the experimental stage because of conflicting theories lack of suitable material for experimentation and difficulty of interpreting results. Besides the involuntary nervous system in the head is so closely fused with the sensory system that selective surgery is almost impossible. Just consider the elaborate network the intricate pathways and the anastomoses between the sensory nerves of the head namely the trigeminus intermedius glossopharyngeus and vagus and the autonomic and sympathetic nerves. I feel that referred pain from deep nasal sinusitis is carried by the system formed by the nervus intermedius geniculate ganglion great superficial petrosal nerve and vidua nerve and the tie-ups these structures have with the trigeminus glossopharyngeus vagus and the sympathetic and autonomic network. Are there any diseases or conditions which can with certainty be said to result from irritation of the cranial and sympathetic nervous systems by any pathologic condition in the ear nose and throat? No. I should like to ask the author to explain why definite clinical improvement in hay fever cases is obtained by any method which temporarily destroys the close contact between the irritating substances and the nerve end organs in the nasal mucosa. I know that this can be answered by saying that this method prevents the sudden shift in acid-base equilibrium as it is a question of mechanical irritation and reflex response. It is true that some cases are benefited by nitrohydrochloric acid therapy but never by that procedure alone and the same holds for the calcium therapy. I believe all rhinologists have noted in cocaineizing an allergic nose when the mucosa is pale and boggy that the cocaine causes a shrinkage of the membranes with a return of a pink color to them. I am sure rhinologists have found a difference in the color of the mucosa on the two sides of the nose when at the same time one side may appear normal in color and the other side may show the allergic picture. Certainly these observations cannot be explained by an acid base shift which presumably affects all sympathetic and autonomic nerves alike. Allergic sinusitis from food allergy I believe more generally conforms to the idea which the author presents.

DR ALBERT KUNTZ St. Louis. It is important to think of the autonomic system as essentially an efferent system. All observations reported which seem to indicate afferent conduction within the autonomic system can be explained on the basis of those afferent fibers of the cerebrospinal system which are associated with the autonomic nerves. It has been pointed out that the autonomic system is not essential to life. Animals have

lived for many months, even years, with their sympathetic trunks removed. That of course effectively paralyzed the entire sympathetic division but not the parasympathetic. The parasympathetic nerves, however, probably are less important than the sympathetic so far as the life of the organism is concerned. The animals that have lived in the absence of their sympathetic trunks have existed under sheltered conditions. They probably would not have fared very well if they had had to make their way as most animals do. It is a different matter for a cat to live in the laboratory than in the back alley. The autonomic nerves play an important part in maintaining the chemical balance of the body fluids. Many questions regarding the acid-base balance and its relation to the autonomic balance remain unanswered, yet it is well to keep that relationship in mind. Along this line lies the hope for improvement in therapy. Little is known regarding the pathology of the autonomic nerves. Furthermore the essential relationships of the autonomic nerves to the central nervous system must be kept in mind particularly those centers within the brain stem that send impulses out through the autonomic nerves. It may be that in many instances the fault is not so much peripheral as it is central. On the other hand sympathetic ganglions removed by operation in cases of arthritis Raynaud's disease and certain other conditions reveal a pathologic condition. The most important changes that have been found include infiltration of the ganglions with white cells changes in the chromidial substance in the ganglion cells and in some cases, phagocytosis of the ganglion cells. I think it can quite safely be said that in all these cases there has been overstimulation of the sympathetic nerves. This also is indicated by the clinical symptoms. Although little can be based on our present knowledge of the pathologic changes found in autonomic ganglions it seems worth while that we should work further along these lines.

THE ETIOLOGY AND TREATMENT OF HEMORRHAGE OF THE NOSE AND THROAT

PRACTICAL CONSIDERATIONS IN RELATION TO OTOLARYNGOLOGY

HENRY M. GOODYEAR, M.D.

CINCINNATI

The value of thromboplastic agents in the treatment of hemorrhage is questioned by many laboratory workers and by some is reported as being nil. There are so many things which influence the time of coagulation that reservation must be given in measuring the evidence offered to support their real value. Experimentally the withdrawal of 4 cc. of blood from a rabbit may decrease the coagulation time for several days. Suffice it to say that any coagulant derived either from blood or from tissue should not be introduced into the vein unless it is protein free as evidenced by the absence of any coagulation on boiling.

The use of ovarian extract in hemophilia is strongly advocated by some and as strongly disapproved by others. The present evidence would indicate that it is worthy of a trial. However the most reliable aid in hemophilias at the time of operation is small blood transfusions one given forty-five minutes before operation and repeated in small amounts (from 150 to 200 cc.) every two or three days. The citrated blood is apparently as satisfactory as a direct transfusion and is easier to give.

Great care must be used always in giving transfusions to decrepit individuals with a low renal output, or in the presence of pulmonary or cerebral edema.

From the Department of Otolaryngology University of Cincinnati College of Medicine.

Read before the Section on Laryngology Otolaryngology and Rhinology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

It is well to remember that transfusion has no value in purpura haemorrhagica. These cases are always accompanied by a loss of blood platelets and may be relieved only by splenectomy, as was recently demonstrated in one of my cases, a young woman who responded neither to thromboplastic agents nor to transfusions.

Hereditary hemorrhagic telangiectasis (Osler's disease) may occur in either the male or the female. The characteristic nevus, as noted in the mucous membrane

Fig. 1—Simple and effective soft palate retractor

of the nose, may also occur in the skin. The chronic acid head is the treatment of choice.¹ Recently I had a typical case under treatment in a man, aged 27.

Pressure on a purpuric spot will not cause it to disappear, the opposite is true of a nevus.

NASAL BLEEDING

Various authors state that at least 90 per cent of all nasal bleeding is from the anterior portion of the nasal septum. Often one sees blood pulsating from an open vessel in this area. I have found that the application of a 10 per cent solution of cocaine, followed by a small application of 50 per cent solution of silver nitrate held against the bleeding point has always been most satisfactory. If the bleeding does not stop immediately, sufficient reaction with swelling usually occurs within ten to fifteen minutes to occlude the bleeding point.

A bleeding vessel from the posterior floor of the nose is often difficult to locate. Here again an application of from 50 to 100 per cent solution of silver nitrate held with pressure against the posterior two thirds of the floor may strike the bleeding point. A swelling reaction quickly follows, often with cessation of bleeding, without resort to packing.

The use of continuous irrigation with ice water in bleeding from a point high or posterior in the nose is not to be forgotten, especially when high blood pressure is present.

Alexander in his clinic in Vienna, recommended the use of 5 cc of a 10 per cent salt solution in the vein for nose and tonsil bleeding. Often the bleeding stops within ten minutes.

From 10 to 20 cc of the patient's own blood given in the gluteal muscles often acts quickly. Skillern² reports this procedure in twenty minutes if the first injection fails.

Recently my colleague Dr. F. U. Swing experienced a general intractable oozing from both tonsil fossae shortly after operation. Packing thromboplastics and

transfusions failed. Finally 10 cc of warm whole blood from a donor was injected under the scapula with almost immediate cessation of hemorrhage.

Severe bleeding from the anterior or posterior ethmoid arteries in ethmoid operations can usually be controlled by packing.

SPHENOPALATINE ARTERY

The sphenopalatine artery runs under the mucosa on the anterior wall of the sphenoid and occasionally on the anterior floor of this sinus. It is this vessel that is most frequently injured in cutting down the anterior wall of the sphenoidal cavity.

Bleeding may occur immediately or days after the operation and usually streams from the nose in a most alarming manner, making it impossible to locate the bleeding point. It has been my experience that one half inch iodoform packing generously packed in the region of the mouth of the sphenoid has always been successful in these cases. I shall cite two rather recent examples.

CASE 1—Mrs. C. T. K., aged 39, underwent an operation in which the right sphenoid was opened with downward biting forceps. One hour later I saw the patient with blood streaming from the nose. She was pale and faint and had lost what looked like a pint or more of blood. A quantity of iodoform gauze was quickly inserted and pressure applied over the corresponding carotid artery. Bleeding ceased almost immediately and the packing was removed twenty-four hours later without further trouble.

CASE 2—Miss L. P., aged 28, had an ethmoid sphenoid operation. Severe bleeding occurred suddenly five days later. The condition was critical when seen. Iodoform packing stopped the bleeding which recurred on each attempt at removal until the seventh day, when all packing was removed.

Yankauer³ advocated the peeling off of the mucosa from the anterior surface of the sphenoid and then crushing the tissue, including the artery, with heavy

Fig. 2—Sigmoid tortuosity of left internal carotid (Skillern)

curved forceps, while E. Sewell and F. Smith advocate suture ligation in all complete external ethmoid sphenoid operations.

What branch of the carotid shall be ligated in intractable nasal hemorrhage? There are many reports of the ligation of the common carotid artery, but comparatively few reports of ligation of the external carotid.

¹ Hauser, K. M. Hereditary Hemorrhagic Telangiectasia. *Ann. Otol. Rhin. & Laryng.* 43: 721 (Sept.) 1934.
² Skillern. Personal communication to the author.

³ Yankauer, S. The Complete Sphenoid-Ethmoid Operation. *Laryngoscope* 31: 831 (Nov.) 1921.

In selecting the vessels to be ligated it is to be remembered that the entire blood supply of the nose is from the external carotid artery. The only exception is the upper part of the nose which is supplied by the anterior and posterior ethmoid branches of the ophthalmic, which in turn arises from the internal carotid artery.

Fig 3—Diagram of the blood supply to the faucial tonsil (Davis)

Thus it is evident that the far less formidable procedure of tying the external carotid artery is the logical procedure in persistent nasal bleeding.

Collateral circulation is quickly established in from four to five days, and ligation of both sides, if necessary, would produce only temporary anemia.

CASE 3—A man aged 56 who was referred to me because of nasal bleeding, had a malignant neuro-ectodermal tumor in the sphenoid area. There were persistent nasal hemorrhages in which a ligation of the external carotid artery produced no apparent slowing of bleeding, but pressure on the opposite carotid caused the bleeding to stop.

ADENOID BLEEDING

Insufficient attention is given to adenoid bleeding at the time of tonsil and adenoid operations. Often the operator will meticulously dry the tonsil field yet let the patient leave the table with blood dripping from the nose. An adenoidectomy is as important as a tonsillectomy, and no adenoid operation should be considered complete without retraction of the soft palate and direct examination. Any bleeding points should be caught with curved artery forceps and the field completely dried before the patient leaves the table (fig 1).

Bleeding not infrequently occurs from six to ten days after the operation at which time the clot which usually extends into the pharynx should be removed and 1:1000 epinephrine dropped through the nose. The child is requested to sit up and bend slightly forward. If this treatment fails a gauze plug may be drawn into the nasopharynx or an anesthetic given and the area dealt with directly.

TONSIL BLEEDING

Not many laryngologists have had a death from hemorrhage following a tonsillectomy or incision of a peritonsillar abscess, yet such an accident is not unknown as is evidenced by a review of the literature.

Normally the internal carotid artery is one-half inch lateral to and three-fourths inch posterior to the tonsil. However, tortuosity of this vessel (fig 2) may bring it in intimate contact with the only interposing barrier, the superior constrictor muscle, which is often very thin, indeed almost wanting.⁴

In mammalia the internal carotid is often more tortuous than in man. Fisher⁵ quoting Chauveau, says that the internal carotid of the seal is actually forty times as long as the distance it has to traverse.

Schaeffer states that the internal maxillary and lingual arteries may be dangerously near the lower pole of the tonsil. Indeed, a high curving of the superior thyroid artery may be in contact with the inferior pole of a large tonsil, particularly in a high division of the common carotid.

There are five arteries supplying the tonsil, all branches of the external carotid artery, namely (1) facial, (2) lingual, (3) internal maxillary, (4) ascending pharyngeal and (5) descending palatine (fig 3).

Since all these vessels are from the external carotid this would be the vessel ultimately to be tied in an emergency.

In every hospital where tonsillectomies are performed, an emergency tray should be set up and ever ready. A number 4 pharyngeal mirror is unsurpassed for turning out the blood clot. One is pleasantly surprised at its smoothness. A tonsil syringe and an injection of procaine-epinephrine are great aids in clearing the field and add greatly to the comfort of the patient while a bleeding vessel is being dealt with.

Delayed postoperative hemorrhages are rather to be expected when nose and throat operations are done in the presence of an acute infection.

RETROPHARYNGEAL AND PERITONSILLAR ABSCESES

One may have treated many retropharyngeal and peritonsillar abscesses without mishap, but when a sudden, often fatal, hemorrhage does occur one is shocked.

Fig 4—Outline of retropharyngeal abscess in a child aged 11 months (Cincinnati General Hospital)

with the importance of having a definite idea as to diagnosis and treatment. The operator asks himself whether it is the internal or the external carotid artery that has been eroded and which vessel should be tied or should the common carotid be tied? In what cases will unnecessary ligation of a major vessel be avoided?

⁴ Schaeffer, J. P. Aberrant Vessels in Surgery of the Palatine and Pharyngeal Tonsils. *J. A. M. A.* 77: 14 (July 2) 1921.

⁵ Fisher, A. G. T. Sigmoid Tortuosity of the Internal Carotid Artery and Its Relation to Tonsil and Pharynx. *Lancet* 2: 128 1915.

In suppurative cellulitis following such illnesses as scarlet fever it is the internal jugular and not the carotid vessel that is usually eroded⁶

RETROPHARYNGEAL ABSCESS

Although retropharyngeal abscess is relatively infrequent (41 cases in 33,892 new cases admitted to the hospital for sick children, Toronto), more careful examination of the larynx in infants with fever, swellings in the neck and difficult breathing would reduce complications.

I would emphasize lateral roentgenograms of the neck in infants, the outline of precervical swellings (fig. 4) is impressive.

The incision of the abscess should not be taken lightly, as is attested by the number of deaths reported at operation. I have made it a practice to aspirate first with a large syringe and needle. I have removed as much as 20 cc of pus before making the incision, thus greatly reducing the danger of immediate complications.

Fig. 5—Horizontal section through mouth and pharynx at the level of the tonsils. Arrows A and B indicate point of entrance to the pharyngomaxillary space used respectively in two of my cases.

Immediate pressure over the carotid artery, on the side of the abscess at the time of bleeding, may save the patient while preparations are being made to ligate the common carotid artery. This occurred in one of my recent cases.

CASE 4—A child, aged 4 years, had a retropharyngeal abscess which had been opened and rather a sharp hemorrhage of several ounces of blood occurred during the night. At 11 o'clock the following morning a sudden severe hemorrhage occurred and respiration ceased. A tracheotomy was done and artificial respiration started. Bleeding was checked by pressure on the carotid but recurred as soon as the pressure was released. With the bleeding retarded I was able to ligate the common carotid. The recovery was excellent.

When sudden severe expulsion of blood occurs in the presence of a retropharyngeal swelling either

before or after incision, no time should be lost in ligating the common carotid on the same side, for at any moment the hemorrhage may recur with fatal results.

A number of cases in the literature are reported in which sudden, severe hemorrhage has occurred through the external auditory meatus, a grave symptom, the abscess eroding into the external auditory canal or into the eustachian tube. Immediate ligation of the common carotid is indicated.

PERITONSILLAR AND PHARYNGOMAXILLARY SUPPURATIONS

Bleeding from a tonsillar infection with moderate intermittent attacks of bleeding, with no definite pharyngomaxillary symptoms, justifies the removal of the tonsils and a search for the bleeding point.

CASE 5—A man aged 22, had a history of sore throat, difficulty in swallowing, and pain over the right side of the neck.

Pain and difficult swallowing were allayed, but eight days after onset from 2 to 4 ounces (60 to 120 cc) of fresh blood was expectorated. These hemorrhages recurred at intervals of from six to twelve hours for four days. There was no definite peritonsillar swelling so I decided to remove the tonsil, which was large, under local anesthesia. There was no bleeding requiring ligation and no further incident of bleeding in the recovery.

Peritonsillar abscesses usually occupy the supratonsillar space and can be drained by the usual incision. This is the case with marked peritonsillar swelling, which I increase but get little or no pus and which often gives distressing neck complications later.

I believe that more frequent radical and early removal of a tonsil should be resorted to in cases in which no relief is given by incision and general distress and neck symptoms continue or increase out of all proportion to the usual reaction to a peritonsillar infection.

CASE 6—A man exhibited a peritonsillar swelling which was incised without relief. Marked swelling of the neck occurred with symptoms of jugular thrombosis. Dr. Iglauder explored the neck but no abscess or infected vessel was found. The tonsil was then removed and a quantity of pus obtained.

Early drainage of the pharyngomaxillary space, once pus is established, is important in saving the carotid vessels from erosion. This space when distended can be readily opened through the throat (fig. 5), as I was able to demonstrate in two of my private cases.

Repeated sudden hemorrhages of from 4 to 8 ounces (120 to 240 cc) of blood in the presence of a peritonsillar infection with definite swelling in the neck often increases as soon as the hemorrhage stops indicating erosion of a major vessel, and no time should be lost in ligation before a final and fatal hemorrhage ensues. The common carotid should be ligated. Statistics show that this is the only effective treatment.

Back circulation may occur through the external carotid after the common carotid has been tied, which happened in one of my cases necessitating a second operation to ligate the external vessel.

LIGATION

The terms external and internal carotid are rather misleading, applying rather to their relation to the inside and outside of the skull than to their relative

⁶ Salinger, Samuel and Pearlman, S. J. Hemorrhage from Pharyngeal and Peritonsillar Abscesses. Arch. Otolaryng. 18:464 (Oct.) 1933.
⁷ Wishart, D. E. S. Retropharyngeal Abscess and Erosion of Internal Carotid Artery with Pathological Specimen. Canad. M. A. J. 13:635 (Sept.) 1923.

positions in the neck. Textbooks do not emphasize the point that the internal carotid actually lies more superficial than the external at and just above the point of bifurcation (fig 6). Thus I have seen this vessel mistaken for the carotid at operation, and not until the dissection was carried deeper and medially was the external carotid with its branches identified.

The incision should extend from the angle of the jaw downward along the anterior border of the sternomastoid muscle for a distance of from 2 to 3 inches (5 to 7.5 cm). Mosher⁸ stated that the important landmark is the tip of the great horn of the hyoid bone, the external carotid lying external to it.

Most textbooks indicate that the bifurcation of the common carotid is at the upper border of the thyroid cartilage, but it is well to remember that the bifurcation may occur even above the angle of the jaw, as was

Fig 6—Dissection showing the lateral prominence of the internal carotid artery. A common carotid B external carotid C internal carotid D ascending pharyngeal E internal jugular vein and F facial vein.

evident in one of my recent dissections. This would have been of tremendous importance to one who was attempting to ligate this vessel. Barnhill⁹ reported that thirteen of twenty-three cadavers showed bifurcations above the thyroid bone and two under the angle of the jaw.

SUMMARY

- 1 Reservation must be given in measuring the true value of thromboplastic agents.
- 2 Ovarian extract is worthy of a trial in hemophilia; however, blood transfusions are the most reliable.
- 3 Blood transfusions have no value in purpura haemorrhagica; splenectomy may offer the only relief.
- 4 Hemorrhagic telangiectasia responds best to the chromic acid bead.

⁹ Barnhill J F. read before the American Laryngology, Rhinology and Otolaryngology Society in June 1915.

5 Ten per cent cocaine followed by 50 per cent solution of silver nitrate is most satisfactory in hemorrhage from the anterior nasal septum.

6 Gauze packing in the region of the anterior wall of the sphenoid is effective in bleeding from an injured sphenopalatine artery.

7 In intractable nasal hemorrhages the external carotid artery should be ligated.

8 Insufficient attention is given to adenoid bleeding at the time of operation. No adenoid operation should be considered complete without retraction of the soft palate and direct examination for bleeding points.

9 Since all branches supplying the tonsils are from the external carotid artery, this would be the vessel ultimately to be tied in an emergency.

10 In suppurative cellulitis following such illnesses as scarlet fever, it is the internal jugular vein and not the carotid vessels which is eroded.

11 Retropharyngeal abscess is relatively infrequent and always a potentially dangerous complication, as is attested by the number of deaths reported. The pus should be aspirated first and then the incision should be made.

12 Immediate pressure over the carotid artery, on the side of the abscess at the time of bleeding, may save the patient during the preparation to ligate.

13 Bleeding from a tonsillar infection with moderate intermittent attacks of bleeding with no definite pharyngomaxillary symptoms, justifies the removal of the tonsil and a search for the bleeding point.

14 When sudden severe expulsion of blood occurs in the presence of a retropharyngeal or peritonsillar swelling, either before or after incision, no time should be lost in ligating the common carotid artery on the same side, for at any moment the hemorrhage may recur with fatal results.

15 When the pharyngomaxillary space is distended with pus it can be drained by incision anterior to the anterior tonsillar pillar, or by incision posterior to the posterior tonsillar pillar.

16 Radical removal of the tonsil is justified after incision of a peritonsillar abscess when little or no pus is found and general distress and neck complications increase rather than diminish. Drainage of a hidden pocket may be thus established.

17 Back circulation may occur through the external carotid after ligation of the common carotid artery.

18 When incision is made for ligation it is the internal carotid that usually comes into view first, before the external carotid is located.

19 Bifurcation often occurs high, even about the angle of the jaw.

ABSTRACT OF DISCUSSION

DR FRANK R. SPENCER, Boulder, Colo. Some years ago I found repeated transfusions of no value in purpura haemorrhagica. Nothing was of any real value. Bleeding began forty-eight hours after tonsillectomy. There were hemorrhages under the skin in the lungs, in the intestine in the urinary bladder and from the tonsillar fossae until the fatal termination. Surgical diathermy is usually more satisfactory for treatment of the hereditary hemorrhagic telangiectasia than the cautery. I have not been successful in controlling hemorrhage from Kiesselbach's plexus with 50 per cent silver nitrate except in mild cases. The actual cautery and surgical diathermy are quicker in their action and more permanent. Hurd has shown that salt pork may be used to advantage for the control of epistaxis, especially when other remedies are not available. I have not had occasion to try this nor have I used Alexanders

injection of salt solution. The injection of from 10 to 20 cc of the patient's own blood in the gluteal muscle is much better than thromboplastic agents. I prefer to control primary tonsillar hemorrhages by suturing the bleeding points at the time of the operation as advocated by Crowe, McReynolds and others except that I try to draw the bottom of the tonsillar fossa together by a few purse string sutures. This avoids most of the delayed primary and secondary hemorrhages. It makes the necessity for ligation of the external carotid rare. Batson's dissections show that in rare cases ligation of the external carotid, or even the common carotid, will not control the hemorrhage, because of anomalous arteries. Ligation of the external carotid artery for severe hemorrhage following a retropharyngeal or peritonsillar abscess should be done earlier than it usually is. Early removal of the tonsils in patients with peritonsillar abscess should be resorted to much more frequently than it is. Tonsillectomy will avoid most of the deep cervical infections. Mosher's demonstrations of the surgical importance of the pharyngomaxillary fossa, the anatomy and surgical approach with ligation of the internal jugular in some cases, have greatly improved the care of these patients. One of the greatest difficulties is that these cases are seen too late.

DR SAM E. ROBERTS, Kansas City, Mo. In the second paragraph of his paper Dr Goodyear made a statement which I am sure he does not mean. He suggested the use of ovarian extract and multiple small transfusions before and after operating on the patient with hemophilia. I do not believe that Dr Goodyear operates on hemophilic patients. In my twenty-five years I have managed to steer clear of them. I usually resort to the procedures Dr Goodyear suggested, the silver nitrate, perhaps a little trichloroacetic acid but when the minor means do not stop the bleeding I resort to Monsel's solution. I know there are those in this group who would say that is damaging to the ciliated epithelium. I have used it many years and have seen no permanent harm. I am going to continue using it. It is an effective remedy. I have found the injection of from 20 to 30 cc. of freshly removed human blood into the gluteal muscles of the patient quite effective in controlling the bleeding. I frequently resort to this method in the delayed hemorrhages when the patient is at home or away from the hospital where typing cannot be carried out. I think that many tonsillar hemorrhages might be prevented if immediately after the tonsil is enucleated it is placed back in the tonsillar fossa and held there firmly for two or three minutes. This gives the contact of tissue juices which is quite effective. On the assumption that bleeding occurs after the patient has left the operating room, the routine that I observe is as follows. First to clear out the clot with a ball of cotton dipped in hydrogen peroxide until the whole fossa can be seen. Frequently this is enough to stop the bleeding. If it doesn't stop then pressure from three to five minutes and if this doesn't stop it a Monsel pack is left in place twenty-four hours. I am a firm believer in early transfusions. In all my cases in which I suspect bleeding I have the blood typed before operation. Most of my hemorrhages, however, are surprises the same as yours. You don't expect them but they still bleed so the ones I type seldom have any bleeding.

DR. THOMAS C. GALLOWAY, Evanston, Ill. Among other less common causes of hemorrhage are malignant growths especially transitional cell carcinoma of the pharynx, which may give troublesome hemorrhage from a small growth, leukemia, and uremia which has seldom received mention but which Dr R. A. Jaffe at Cook County Hospital believes relatively common. It is one cause of intractable nasal hemorrhage. I think it should be reiterated that hemorrhage from the posterolateral pharyngeal wall which is sudden and profuse almost certainly must come from the internal carotid artery. Such hemorrhage requires immediate ligation of the internal or common carotid artery. The morbidity of such ligations as given by DeCosta is 25 per cent and the mortality is about 3 per cent. I have ligated the common or internal carotid eight times with one death. Dr Goodyear mentioned bleeding from the external auditory canal as usually meaning involvement of the internal jugular vein and I think he is right. If the hemorrhage is rather profuse and it occurs in relation to deep sepsis even though it can be temporarily controlled it is dangerous and should be treated with much consideration. He suggests liga-

tion of the common carotid. In a recent case I was unable to control it by such ligation, apparently because of the free collateral circulation through the other venous channels of the skull. Dr L. F. McBride had such a case in which he did the much more rational procedure, of exposing and packing the sigmoid sinus, with adequate control. This seems more satisfactory and less dangerous than the ligation of the common carotid artery.

DR HENRY M. GOODYEAR, Cincinnati. Dr Spencer spoke of purpura haemorrhagica, which of course, is not relieved by transfusions, and, as happened in one of my cases this past winter, after trying various things, splenectomy became imperative. Concerning substances for bleeding from the anterior portion of the septum many have been recommended. I use a small applicator with 50 per cent silver nitrate, and so far I have not had any cases in which it did not succeed when the bleeding point was evident. So far as bleeding in uremia is concerned, I have had no experience.

DISSEMINATED POLYPOSIS OF THE COLON

A NEW SURGICAL TREATMENT IN SELECTED CASES

CHARLES W. MAYO, MD
AND
E. G. WAKEFIELD, MD
ROCHESTER, MINN.

In the nomenclature of intestinal tumors the term "polyp" is useful in describing what is seen with the unaided eye. That is, it is a gross anatomic term and is not intended to indicate the probable histologic structure of the tumor. Polyps of the rectum and colon vary in size from small excrescences on the mucous surface (fig. 1) to pediculate tumors of varying size (fig. 2). Between these two extremes there are many variations in the gross appearances of these tumors. If histologic examination reveals that the polyp is an adenoma, it is proper to designate the condition as "adenomatosis of the colon." The general employment of the term "adenomatosis" to designate a polyposis of the colon is likely to create confusion unless microscopic examination has revealed the adenomatous nature of the lesion. Not all polyps of the colon are adenomas.

The classification of polyps of the colon is not all that is to be desired, as the present knowledge of their cause is not sufficient to permit them to be classified. For the sake of clearness the so-called classifications of polyps of the colon proposed both by Erdmann and Morris¹ and by Wesson and Barger² should be mentioned. Erdmann and Morris divided polyps of the colon into two groups: (1) those which are congenital or adolescent in origin and (2) those which are acquired. Wesson and Barger divided these growths also into two groups: (1) postinflammatory polyps and (2) true polyps. Both of these classifications take into consideration what is apparently true, there are two types of polyps of the colon. The polyps of the colon that Erdmann and Morris classified as congenital or adolescent in origin are recognized by Wesson and Barger as true polyps. Therefore there is an apparent agreement between these authors that the rest of the polyps of the colon are acquired. Both of these clas-

fications lack proper qualifications, since no patient was ever known to have been born with a disseminated polyposis of the colon, and the relation of polyposis of the colon to infection is not known. It is only necessary to point out that in the cases which are reported here the polyps belong to the congenital or adolescent group of Erdmann and Morris or to the true polyps in the classification of Wesson and Bargent.

Polyposis, or excrescences on the mucous membrane of the colon, has been described in the literature since the early part of the eighteenth century. The most convincing report by an early writer is that of Luschka,³ who described thousands of polyps of varying size which occurred in the colon of a woman aged 30. The polypoid lesions which had been described previously by other writers were termed "colitis polyposa" by Virchow⁴ in 1863. Cripps⁵ was the first to record that the disease may affect different members of the same family. Lockhart-Mummery,⁶ Erdmann and Morris,⁷ Gant,⁸ Storey,⁹ Pennant,¹⁰ Kennedy and Weber,¹¹ and others have reported more than one instance of polyposis of the colon among members of the same family.

The disease is usually manifested in early adult life at about the age of 30 years, however it does occur

Polyps may occur throughout the lumen of the alimentary tube. However the process is usually limited to anatomic divisions such as the stomach, small intestine or colon. Aside from patients who have disseminated polyposis of the colon there are many patients who have one or more polyps in the rectum or rectosigmoid. In addition to the patients who have a few polyps in the rectum and rectosigmoid and those who have a disseminated polyposis there are those who have segmental polyps, which usually are situated at the flexures of the intestine. It is important to remember that a polyp of the intestine may prove serious in one of four ways: (1) It may bleed as a result of infection or ulceration, (2) it may obstruct the intestine when it has attained sufficient size, (3) it may produce an intussusception, and (4) most important of all, it may become malignant, if carcinoma is not already present when the polyp is first discovered.

Hullsiek¹⁴ found that the average age of patients who had polyposis of the colon is 30.9 years. It therefore is evident that some of Hullsiek's patients must have been a decade or more on either side of 30 years of age. This illustrates that it is impossible to determine whether the condition is congenital or acquired in cases in which the patients are 40 or more years of

Fig 1—*a* small excrescences (polyps) on mucous membrane of colon *b* cross section of such polyps (X 3)

much earlier. Vajda,¹¹ Bickersteth,¹² Niernack,¹³ and Kennedy and Weber have reported cases of disseminated polyposis of the colon in which the patients were 12 years of age or younger. Kennedy and Weber had a patient 2½ years of age.

So far, no one has offered any criteria for settling this point, which is, of course, purely of academic interest.

In some cases of severe ulcerative colitis in which there has been widespread destruction of the intestinal mucosa the colon may have a polypoid appearance. Some of the polypoid projections are true polyps while others are puckered projections of the intestinal mucosa. While this appearance may be the result of ulcerative colitis we have seen polyps of the colon which had undergone degeneration with widespread infection and which were indistinguishable from severe ulcerative colitis. We have seen characteristic chronic ulcerative colitis develop in two cases of disseminated congenital polyposis of the colon. Examination of segments of the intestine which were removed surgically, revealed evidence of chronic ulcerative colitis. All the original polyps had disappeared probably as a result of the destruction and ejection of the mucous

membrane that occur in the latter condition. We know of no cases previously recorded in which there was a disseminated polyposis of the colon with a subsequent development of a chronic ulcerative colitis and disappearance of the polyps.

There is a common opinion abroad that polyps of the rectum and colon are rather common. This may be true, but it is hardly substantiated by the objective data. In the proctoscopic examination of the rectum or rectosigmoid of 4,000 patients in the Proctologic Clinic of St. Mark's Hospital in London, Allingham¹⁵ found sixteen patients who had polyps. Of the patients examined in the Section on Proctology at the Mayo Clinic 4 per cent had one or more polyps that could be

of the nineteen patients were women and seven were men. The average age of the patients was 29.1 year. Carcinoma was known to be the lesion for which the patient was sent to operation in six cases. The presence of blood in the stools, which usually was intermittent usually was the symptom that caused the patient to seek relief. Diarrhea was more constant from day to day than was the blood in the stools. The diarrhea varied and frequently was characterized by acute exacerbations. During these exacerbations the number of rectal discharges were as many as fifteen to twenty in twenty-four hours. A mild cramplike pain in the lower part of the abdomen which was increased during and after bowel movements frequently was present. Moderate

to severe anemia was present in most of the cases. In about a third of the cases the number of leukocytes was greater than 10,000 per cubic millimeter of blood.

The general physical condition, aside from the varying degrees of anemia, was good. A presumptive diagnosis of polyposis of the colon was made in all cases by digital examination.

REPORT OF CASES

The clinical data in two of the nineteen cases will be summarized briefly.

CASE 1—A woman, aged 41, had enjoyed good health until the onset of the present illness, three years before she came to the clinic. The present illness began with a discharge of small amounts of bright red blood and mucus with each bowel movement. During the first year of her illness the discharge of blood and mucus in the stools had not caused a great deal of concern, since she had felt well and there had not been any change in her normal passage of two stools each day. In the second year of her illness the discharge of blood and mucus had become more profuse, an intermittent diarrhea (up to twelve stools daily) had developed and she had had diffuse dull aching abdominal pains which often were more severe just before bowel movements. During the year before she came to the clinic, the third year of her illness, the diarrhea had continued but there had been a decrease in the amount of rectal bleeding. Throughout the illness her weight had remained normal. At times there had been "a little temperature" but there was no very definite history of pyrexia.

General examination revealed that she was a small woman, 5 feet 2 inches (157.5 cm) tall and weighed 111 pounds (50 kg). The skin and mucous membranes were definitely pale and she complained of weakness. There was tenderness over the distal segments of the colon. A digital examination of the rectum revealed a hard palpable roughened surface of the rectal wall. Sigmoidoscopic examination disclosed a disseminated polyposis of the rectum and rectosigmoid. Rectosigmoidoscopic examination revealed polypoid lesions disseminated throughout the large intestine. Aside from a definite secondary anemia (the value for the hemoglobin was 9.5 Gm. per hundred cubic centimeters of blood) the results of laboratory tests were within normal limits. The surgical treatment of this patient was carried out precisely as is outlined in this communication.

Fig. 2.—a long pedunculate polyp of colon b cross section of such a polyp (slightly reduced from a photomicrograph with a magnification of 5 diameters)

visualized with the sigmoidoscope. Only 0.04 per cent of the latter group had a disseminated polyposis of the colon.

In the nineteen cases which form the basis of this paper, disseminated polyposis extended from the terminal portion of the ileum to the rectum. The diagnosis in all these cases was confirmed by examination of a segment of colon after it had been removed surgically. None of the patients in these cases were more than 41 years of age. This upper age limit was arbitrarily selected since there are no other criteria for the selection of cases of congenital polyposis of the colon and the upper age limit has not been defined. Twelve

¹⁵ Allingham, William. *Diagnosis and Treatment of Diseases of the Rectum, Anus and Contiguous Structures*. Philadelphia: F. A. Davis Company, 1888, p. 189.

Recovery from the operations was uneventful. Six months after the last operation the patient was well.

CASE 2—A woman, aged 22, came to the clinic on account of diarrhea, which had been present for several years. She never had had more than six or eight stools in twenty-four hours. Eighteen months before she came to the clinic she had had a constant aching pain in the lower part of the abdomen and in the perineal region. This perineal pain had been most severe before bowel movements. Recently the abdominal pain had become severe and cramplike and, like the perineal pain, had become most severe just before defecation. During the past year small quantities of bright red blood occasionally had been present in the feces.

She was healthy in appearance except for a slight paleness of the skin and mucous membranes. Along the distal segments of the colon was a moderate amount of tenderness on palpation. The rectal wall felt "rough" on digital examination. Proctoscopic examination revealed a disseminated polyposis. Roentgenologic examination showed that the polypoid lesions involved the entire colon as far proximally as the ileocecal junction. The value for the hemoglobin was 121 Gm per hundred cubic centimeters of blood, the results of the other laboratory tests were within normal limits.

Treatment was instituted as described in this communication. The recovery was uneventful until the twenty-seventh day after ileosigmoidostomy and right hemicolectomy, when signs of intestinal obstruction developed. On the twenty-ninth post-operative day it became urgent that the obstruction be relieved. The abdomen again was opened and an obstruction of the ileum, which was situated about 6 inches (15 cm) from the opening into the sigmoid flexure, was found and relieved. During the operation the pulse rate became greatly increased and 200 cc of 6 per cent solution of acacia and 200 cc of citrated blood were administered intravenously. She continued to fail and died the following day.

COMMENT

We have reviewed the data pertaining to the incidence of cancer or polyposis of the colon among members of the families of these nineteen patients. Ten of the patients did not know positively about the grandparents on one or both sides. If their grandparents had died of cancer, the patients never had been told. Nine knew their grandparents. Of the seventy-six grandparents, three were known to have had cancer. Of the thirty-eight parents, five were known to have or to have had cancer. Two aunts and two uncles had or had had cancer. To adopt the term "sibships," which has been used by Garrod¹⁶ to designate brothers and sisters of the same marriage, ten sibships out of the total of seventy had or had had cancer. Exclusive of the patients, cancer occurred eighteen times among 207 individuals.

These data are not presented as an accurate record of the family histories of these patients but are as accurate as we have at the present time. We do not present these data as proof of a heredity factor of cancer and polyposis of the colon. We do not believe that these data have any significant interpretation or that there is any biologic or genetic theory that makes these data significant.

The diagnosis of disseminated polyposis of the colon cannot be made on the basis of any single finding. The various sized polyps often can be felt by digital examination of the rectum. Proctoscopic examination of the rectum, rectosigmoid and distal part of the sigmoid flexure will reveal that the mucous membrane is studded with polyps which vary from 5 mm to 1 cm or more in diameter. Some of the larger polyps may be pedunculate. Sometimes the polyps appear to be equally dis-

tributed over the surface of the intestine. In other cases the polyps are collected together in groups. The extent of the involvement of the proximal portion of the sigmoid flexure and the rest of the colon may be determined by means of thorough roentgenologic investigation of the large intestine or by direct examination. The extent of the polyposis of the colon in the cases which are the basis of this study was determined by direct examination.

The two conditions that are difficult, clinically, to distinguish from polyposis are cancer which is situated in the rectosigmoid or higher in the bowel and chronic ulcerative colitis. We have seen polyps develop in the course of a chronic ulcerative colitis and chronic ulcerative colitis develop in a colon which was the site of a polyposis. It has been repeatedly observed by us, as well as by others that polyps may degenerate, ulcerate and become infected secondarily. When such a process is taking place, it may be difficult to make a definite diagnosis. Treatment should never be delayed beyond the time necessary to make the diagnosis. We recognize that the surgical risk is greatly increased by the presence of widespread inflammation in a colon that contains degenerating polyps, but we further recognize the fact that delayed extirpation of the colon may jeopardize the patient's chance of recovery if cancer is present. We do not believe that polyps of the colon bleed until infection and ulceration are present. Therefore delay in the institution of treatment is not conservative but perhaps the most radical course that could be pursued.

The treatment of disseminated polyposis of the colon is a surgical problem. This assumption is based on the well known fact that all polyps of the colon may eventually become malignant. Aside from the development of malignancy they are a source of danger, as they may produce intestinal obstruction or hemorrhage and may predispose to inflammatory complications, such as ulcerative colitis.

The development of the treatment of disseminated polyposis is a most interesting study. In the beginning of surgical treatment of this disease, it was observed that ileostomy, which usually was performed late in the course of the disease, merely prolonged an unfortunate existence. To accomplish anything of permanent value, it soon was apparent that the development of a method for removing the affected portion of the bowel was of paramount importance. As surgical technique improved and, with it, the proper preparation of the patient for such hazardous operations, ileostomy, followed by total colectomy, became the method of choice. At best, the risk of ileostomy followed by total colectomy, even when total colectomy is performed in stages, is high and the results are not all that are to be desired. In addition, even when the procedure is successfully accomplished, many patients are left with a more or less troublesome ileac stoma although many get along remarkably well.

Those interested in the treatment of diseases of the colon were anxious that means be developed to preserve the natural outlet of the bowel whenever possible, in cases of multiple polyposis. With the evolution of diathermy and its application in diseases of the rectum, it became possible to fulgurate and clear the rectum of offending polyps. The next steps forward, although not applicable in all cases by any means, were temporary ileostomy, colectomy or the removal of the colon down to the rectosigmoid in one or two stages,

16 Garrod A. E. *Inborn Errors of Metabolism* ed 2 London H. K. Frowde and Hodder and Stoughton 1923

and the transplantation of the ileum into the rectum or the rectosigmoid by side-to-side, end-to-side or end-to-end anastomosis at a subsequent operation. Prominent among the surgeons who have devised such procedures are Rankin¹⁷, Graham,¹⁸ Soper¹⁹ and Struthers²⁰.

The method of treatment which we wish to describe seems to have qualifications which still further advance

Fig. 3—Various stages of ileosigmoidostomy and colectomy

the care of selected patients who have multiple polyposis of the colon. The normal outlet of the rectum and its sphincters is preserved, and the rectosigmoid and sigmoid flexure, which contain the nervous mechanism which controls the desire to defecate, are left intact, thus leaving sufficient room for the storage of fecal material. Primarily, the operation has been made possible by the development of improved instruments and improved technic on the part of proctologists. We were assisted by Dr. Buie and his colleagues in the Section on Proctology at the Mayo Clinic, who removed the polyps from the rectum, rectosigmoid and sigmoid in order that segments which were free of polyps might be utilized in performing an ileosigmoidostomy. The first stage of the operation (fig. 3) is performed by the proctologist, who with repeated applications of diathermy removes a few polyps at a time as conditions permit until the rectum and rectosigmoid are free from polyps. The second stage (fig. 3) of the operation is not performed until the rectum and rectosigmoid are free from polyps and the inflammation incidental to their removal. This stage of the procedure, which is performed through a right rectus incision, consists of end-to-side ileosigmoidostomy and hemicolectomy, with removal of the right half of the colon and as much of the transverse colon as can be easily accomplished. Care is taken in the performance of the ileosigmoidostomy to cut the ileum at an angle (fig. 4) that insures not only a large stoma but also a good blood supply to the incised edge. The anastomosis is made along the longitudinal band with a serous layer of silk sutures and mucosal layers of sutures of chromic catgut, the angles of the anastomosis are protected with extra

interrupted sutures of silk which should include epiploic tags whenever possible. The incised end of the remaining portion of the transverse colon, with a Pavl clamp closing it, is brought out of the upper part of the right rectus incision, after intra-abdominal raw surfaces have been covered with peritoneum. A rectal tube is fixed in the rectum to allow free passage of liquid and gas.

The third stage (fig. 3), which is carried out as soon as conditions indicate, consists of hemicolectomy again, this time through a left rectus incision, with removal of the remaining portion of the transverse colon, the splenic flexure and the descending colon. One can judge the amount of colon to be resected by palpation of the polyps. It may be possible to save more of the colon than has actually been reached from below with the sigmoidoscope, because the proximal portion of colon is brought out of the wound, which makes it possible to fulgurate when necessary through the colonic stoma at a later date. It is important in performing resection of the transverse colon to preserve as much of the omentum and its blood supply as possible. The fourth stage (fig. 3) consists of retrograde examination and fulguration through the abdominal colonic stoma. The fifth step (fig. 3) consists of closure of the colonic stoma, which reestablishes the continuity of the intestine.

Strangely, little if any fecal drainage occurs through this colonic stoma at any time before closure. It may be left as a safety valve for some time and closed later

Fig. 4—Anastomosis of ileum with sigmoid flexure.

after repeated examination has revealed that the remaining portion of bowel is free from polyps.

A word before summarization as to the type of case to which this procedure is applicable. It cannot be used when secondary inflammation has involved the entire colon. In such a case the condition is best treated by ileostomy and total colectomy in stages after the inflammation has subsided. The surgical treatment outlined is of particular value in the case in which the diagnosis

has been made before complications occur, particularly when carcinoma has not involved the colon distal to the sigmoid flexure

As soon as multiple polyposis of the colon is diagnosed and the described method of treatment is considered applicable, the first stage of the operation should be started. While this admittedly is a formidable surgical procedure, it is the only known way of guarding the patient against repeated intestinal hemorrhages and carcinoma. In most cases instead of being a prophylactic measure, the operation actually extirpates degeneration of the polyps, with subsequent infection multiple carcinomas which are already present in polyps scattered throughout the colon.

SUMMARY

In nineteen cases in which the patients were less than 41 years of age, twelve were women and seven were men. The hereditary and familial tendencies if present do not admit of any known genetic or biologic interpretation. Six of these patients had a carcinoma, which was the predominating lesion at the time of operation. It has been said that the development of carcinoma in these colons is inevitable, that uncomplicated polyposis of the colon is symptomless, and that diarrhea and blood in the stools are not signs of polyposis but are evidence of serious complications such as secondary infection, ulceration or carcinoma. An ulcerative colitis may develop on an existing polyposis of the colon with subsequent disappearance of the polyps. The new surgical procedure is designed to reduce the operative risk, conserve the distal segment of the colon and the entire rectum, and eliminate the necessity for permanent ileostomy.

ABSTRACT OF DISCUSSION

DR. FRANK H. LAHEY, Boston. I would like to call attention to the factor of malignancy as established and the accepted need for surgery in these cases. One should be careful about advocating too much x-ray therapy. It seems unlikely that much will be accomplished in the way of cures and that if the dosage is increased sufficiently a good deal of damage will be done without the danger of malignancy being really offset. It seems to me very probable that the x-rays may have considerable value in the preparation of some of these cases. There are certain things that have been learned regarding the surgical management of these cases. One is that no one can standardize the type of operative procedure. Another is that ileostomy is not such a bad procedure if the colon is taken out. Ileostomy is a terrible thing for any individual to endure if the colon is in. It has been demonstrated to my associates and me however in doing colectomies in a considerable number of cases of ulcerative colitis, diverticulosis and colectomies for persons with multiple polyps that there is a tendency as soon as the fluid absorbing section of the colon is taken out for the contents of the ileum to take on the solid character of the contents of the distal colon. We therefore do not think that ileostomy in itself is such a terrible operation if the colon is to be taken out later. If fulguration is to be done in these cases it is wise not to make the colostomy at that stage; it is much easier to manipulate the fulguration with the colon intact and with its upper end flexible. Many of these patients are below 40 and in excellent condition and I believe that many of them will stand as have our patients total colectomy down to the sigmoid in one stage. One can implant the sigmoid in the upper end of the wound doing also ileostomy and a few weeks later after examination of the upper end of the sigmoid and fulguration of any remaining polyps reestablish the fecal stream by anastomosing the ileum to the sigmoid end to side. We have two patients who have two formed movements a day even though all the colon is out and the ileum anastomosed

to the stump of the rectum. All have learned that we have not been sufficiently aware of the possibility of multiple lesions in the colon, and all of us doing surgery have the obligation to establish not only the diagnosis of malignancy, adenomas or polyps but in every case by contrast enema and proctoscopic examinations, we must be extremely sure that although we diagnose the carcinoma we do not leave behind other coincident lesions. Several times in doing resections of the colon I have seen polyps pop out of the end of the open colon that have not been diagnosed. It is extremely important not only that we remove the lesion but that we are sure that there are no other lesions.

DR. WALTER A. FANSLER, Minneapolis. All persons have an innate dread of a permanent ileostomy or colostomy. For this reason a procedure which avoids a permanent stoma and does not lessen the patient's chances of cure is worthy of consideration. Drs. Mayo and Wakefield have pointed out the possibilities of fulguration of the polyps through a proctoscope from below, an ileosigmoidostomy and colectomy in stages. In certain cases modification of this procedure is necessary. I saw a patient in 1935 with multiple polyposis. Because of inflammation and rigidity in the retroperitoneal portion of the sigmoid, it was impossible to fulgurate from below to a point only slightly above the rectosigmoid juncture—a point too low for an anastomosis with the ileum. After the coagulation had been carried upward as far as possible, an ileosigmoidostomy was done a point being selected in the sigmoid where the polyps were relatively few. At the same time a left inguinal colostomy was done a knuckle of the bowel being brought out but not opened. A week later this was opened a proctoscope was inserted in the distal portion, and the polyps were destroyed to a point where fulguration had been completed from below. Thus the bowel was cleared of polyps to a point well above the ileosigmoid anastomosis. The proctoscope was then inserted into the proximal portion of the colostomy and it was possible to coagulate all polyps as far as the splenic flexure. The final operative procedure was a colectomy, the entire bowel being removed down to the point of the colostomy. The distal opening of the colostomy was closed by inverting the bowel end and dropping it back into the abdominal cavity. The ease with which the polyps were coagulated in the upper segment brought to mind certain other possibilities in selected cases. In some cases of multiple polyposis only the rectum, sigmoid and a portion of the descending colon are involved. In these cases a temporary colostomy followed by coagulation through the colostomy and through the rectum would be less hazardous than a resection of the bowel. Also when the physical condition of the patient or the condition of the colon itself would seem to make the operations of ileosigmoidostomy and colectomy too hazardous the polyp-bearing area could be exposed through one or more colostomies and the polyps fulgurated. The colostomy could be left open as long as seemed necessary to satisfy the surgeon that recurrence was unlikely.

DR. H. W. SOPER, St. Louis. As the authors have said many of the patients with uncomplicated multiple polyposis remain symptomless. The diagnosis may be missed in a general examination. It has been my rule for many years that no general examination of a patient is complete without proctosigmoidoscopy. In a case in which operation was performed twenty-two years ago before the days when fulguration was practiced or anything about diathermy was known, the patient was a boy aged 8 years and the polyps in the rectum and lower sigmoid were pedunculated. They could readily be removed by the old snare and cautery of the base and were successfully removed, an eighth-inch stump being left. Colectomy was then done and the ileum was attached to the stump. Dr. Will Mayo knew of this case and asked me to report it some day and I take this occasion to do so. I saw the patient now 30 years of age a husky young farmer with good motility of the intestinal tract having one well formed stool daily. The x-ray examination showed that the ileum had in a way taken on the function of a colon as it had dilated and slowed down the rate of motility. Apparently one can get along very well without a colon. It interested me that the man's urine was negative for indican.

DR. E. G. WAKEFIELD Rochester, Minn. I should like to make one or two remarks about the function of the colon. It has been said that when the body is deprived of the colon and the patient has an ileac stoma, the lower part of the ileum takes on the function of the colon. This is not true. When a patient is subjected to an ileostomy we have shown in metabolic studies that the kidneys immediately compensate in maintaining the electrolytic balance of the body and maintain this function so long as the patient has an ileac stoma. However, some patients who have an ileac stoma develop more and more control of the ileac dejecta and at some periods of the day may pass semiformal feces. The partial control of the ileac dejecta is similar to that which develops in patients who have a colonic stoma. It may or may not be associated with dilatation of the terminal portion of the ileum. In uncomplicated cases the ileum may not dilate at all. If it does dilate, the dilatation is never greater than about twice the normal size and this dilatation occurs only in its terminal segment, which would not greatly increase its storage capacity.

Clinical Notes, Suggestions and New Instruments

AN APPARATUS FOR URINE ALBUMIN DETERMINATIONS ON A LARGE SCALE

F. T. HUNTER, M.D., BOSTON

In a clinical laboratory receiving from fifty to eighty urine specimens each morning, any apparatus that lessens the time required to perform a given test soon justifies its initial cost. The apparatus illustrated here was devised for such a purpose. It consists of twelve electric soldering irons mounted in a supporting frame and wired in parallel. Releasing the thumb-screws permits the frame to be raised or lowered, sliding up or down on the two uprights. Adjustable guards prevent the soldering irons from being lowered too far into the liquid. The base is a piece of thick brass, wide and heavy enough to give stability and to prevent the apparatus from tipping. Twelve test tubes (pyrex, 150 by 25 mm.) rest in a movable solid wooden block, which has holes, bored to a depth of about 5 cm., to fit them. Cleats at the rear of the base guide the block so that when in place each tube lies immediately beneath a corresponding soldering iron.

Fig. 1—Position of apparatus while boiling

When the test is to be performed each tube is filled with a different urine specimen to an appropriate level. The specific gravity is then read a few drops of glacial acetic acid are added the block is placed under the soldering irons the latter are immersed about 1 cm. in the liquid and the current is

turned on. At the end of from two to two and one-half minutes all the specimens have come to a boil, and those positive for albumin can be seen at a glance. As there is a sharp line of demarcation between the boiled and the unboiled portions of the urine, the albuminous cloud is more easily seen

Fig. 2—Soldering irons withdrawn from the liquid after boiling. Note albuminous cloud in the tenth tube

than when boiling is produced in a flame. The time saving achieved by the apparatus is obvious, the cost of operation negligible. Material for the construction of the instrument costs about \$34.

NONTRAUMATIC SPONTANEOUS SUBAPONEUROTIC HEMATOMA ITS PROBABLE RELATION TO ATYPICAL SCURVY

MICHAEL SCOTT, M.D., PHILADELPHIA

The following case of Barlow's disease (forme fruste of scurvy) is presented because of its striking characteristics and its relative rarity in this country. An Italian girl presented herself to Temple University Hospital Dispensary with a painless, progressive enlargement of the head, which had reached striking proportions within a period of three weeks and at first glance suggested an ordinary hydrocephalus. No complaint aside from the noticeable enlargement of the head was described by the patient or by her family. The child was admitted to the service of Dr. Temple Fay and the neurologic and other examinations proved to be entirely negative. Certain unusual features of the case suggested Barlow's disease, and the subsequent treatment employed for the extensive subaponeurotic hematoma of the scalp completely relieved the condition. The full effect of vitamin C therapy could not be ascertained in this instance, as the blood under the scalp was removed largely by aspiration, and following air injection the remainder rapidly absorbed during her stay in the hospital.

Recently Aballi and Valledor¹ reported two cases practically identical to the one here presented. They cured their patients by feeding them lemon and tomato juice without the need of aspiration.

REPORT OF CASE

A C., an Italian girl, aged 14 years, admitted to the Neurological-Neurosurgical Department of Dr. Temple Fay, Temple University Hospital, Nov. 20, 1935, complained of rapid, progressive and painless enlargement of the head. The child had apparently been well in all respects until two weeks previously, when it was noted that the tissues about the left eye became edematous, the following day the right eye was similarly affected and three days later the swelling about the

Read before the Philadelphia Neurological Society, Dec. 20, 1935.
From the Neurological-Neurosurgical Department of Dr. Temple Fay, Temple University Hospital.
¹ Aballi, A., and Valledor, T. Two Atypical Cases of Barlow's Disease. Bol. Soc. cubana de pediat. 5: 201 (June-Dec.) 1933.

eye spontaneously receded. One week prior to admission the mother noticed that the child's head was becoming rapidly larger, especially about the ears and temples. The patient was said to have fallen on the stairs of her home three weeks before but did not strike her head. She landed on the buttocks but

Fig 1—Appearance of patient on admission to hospital

there was no evidence of injury sustained, and the fall was of trivial character.

The past history was negative for direct trauma to the head. There had been no complaints of headache, vomiting, falling vision, ataxia or mental abnormalities.

Fig 2—Eighteen days later following aspiration of hematoma and correction of avitaminosis

Physical examination revealed an emaciated child of sallow complexion with a triangular head (fig 1) showing bulging in the temporal areas on each side. Palpation of the head revealed a fluctuating mass completely surrounding the vertex which shifted with postural changes and followed gravitational

laws. On deep palpation of the swelling, small, round, irregular, marble-like ridges and exostoses could be felt over the skull surface, more so about the frontal bones. There was no pulsation and no evidence of acute inflammation. All other bones of the body were normal on palpation. The physical and neurologic examination was otherwise negative. There were no masses or areas of ecchymosis and there was no disturbance of the pulmonary, gastro-intestinal or urinary systems.

Urinalysis was negative. Complete blood counts showed a definite secondary anemia, hemoglobin was 11.5 Gm, the red blood cell count was 4,000,000, a leukocytosis of from 12,000 to 13,000 was present with a normal differential count. The platelet count was 269,000. The bleeding time was one minute, the coagulation time was four and one-half minutes and the capillary fragility test was within normal limits. Blood chemistry revealed blood sugar, 107 mg per hundred cubic centimeters, serum calcium, 10.9 mg, serum phosphorus (inorganic), 4.8 mg, icterus index, 4 units, van den Bergh test (direct), negative. The blood Wassermann and Kahn reactions of the patient and the parents were negative. Complete spinal fluid studies were negative.

Five days after admission (November 25) the subaponeurotic space was aspirated and 160 cc. of dark red bloody fluid was removed, following which 140 cc of air was injected in order to determine the character of the bony exostosis palpated. This bloody fluid separated into a cellular and a serous layer.

Microscopic examination of this fluid by Dr F W Konzelmann revealed chiefly old red blood cells. In addition, however, "great clumps of macrophages were noted, richly laden with brown granular pigment and with fragments of red blood cells."

X-ray examination of the skull after removal of a portion of the fluid under the scalp and injection of air to replace it showed a fluid level about both temporal areas, with air between the cranium and the scalp. There was no roentgen evidence of any exostosis or proliferation. X-ray examination of the long bones and chest was negative. Encephalographic studies of the brain were then made to rule out intracranial defects or pathologic changes. These proved to be entirely negative for organic disorders. The brain pattern was normal.

COMMENT

There had been no marked loss of weight. The family is poor and fresh milk, butter, orange and tomato juice were rarely if ever served. The mother stated that her other six children were healthy and had no complaints.

The history of trauma as a cause in this case can be dismissed because of its trivial character and because the head was not injured in the fall. The patient insisted that she fell down, striking only the buttocks, and did not "bump her head." The child noticed owing to the swelling occasioned by the hematoma, that the supporting bars for her eye glasses were tight behind the ears, across the temples and over her nose for a period of at least two months before the noticeable onset of her present condition. The photograph (fig 3) reproduced from the article of Aballi and Vallador illustrates the striking similarity in the cranial contour to the case here reported.

The staff was at a loss for a time to account for the extensive and spontaneous hematoma of the scalp. Dr Lansbury of the medical department had suggested subclinical scurvy as

Fig 3—Reproduction of a photograph of a patient with Barlow's disease whose case was reported by Aballi and Vallador.¹

a possibility Dr Ramirez-Corria of Havana, Cuba, was visiting Dr Fay's clinic at the time and unhesitatingly diagnosed the condition as Barlow's disease, subsequently forwarding the Cuban literature on the subject.

CONCLUSION

In a case of extensive, bilateral, nontraumatic subaponeurotic hematoma atypical scurvy (lack of vitamin C) is suggested as a cause for the condition.

Appropriate recognition of this complication is strikingly absent in the textbook treatises on vitamin deficiencies.

Special Clinical Article

SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM

CLINICAL LECTURE AT KANSAS CITY SESSION

JAMES C WHITE, M.D.

BOSTON

The concept that the autonomic nervous system is concerned purely with motor innervation of the smooth muscle of the viscera dates back to the last half of the nineteenth century and the work of Claude Bernard,¹ Gaskell² and Langley.³ In recent years the antagonistic action of the cramosacral and the sympatho-adrenal systems has been intensively investigated by the physiologists and Cannon⁴ gave it the appropriate name of homeostasis. Through this efficient and entirely automatic mechanism, the body adapts itself to the constantly fluctuating stresses and emotions of life. Without it, as Cannon has shown, life is still possible in a perfectly protected environment. But all forms of active endeavor and conflict with unfavorable reality are no longer possible.

It has been known for many years that the action of this system of nerves is not under the control of the will but is under the control of the emotions. More recently the centers from which the autonomic impulses spring have been traced to the premotor cortex and the hypothalamus. Certain disease states are now recognized as arising out of an abnormal activity of the autonomic nervous system. There are also numerous other conditions amenable to treatment by sympathectomy. One of these is visceral pain, which is not actually transmitted over sympathetic neurons but over somatic sensory fibers intermingled with them. As this subject does not, strictly speaking, come under the title of my paper and is too broad to cover here in any detail, I shall have to limit this discussion to the diseases concerned with disordered vasomotor or visceromotor function and confine myself to those which are best known and which have the most definite clinical application.

VASOMOTOR DISORDERS

Human hands and feet like the ears of the rabbit, have the specialized function of regulating body heat.

Read in the General Scientific Meetings at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 12, 1936.

Frazier, Alpers and Lewy⁵ have shown that, when the governing center of this mechanism is destroyed by injuries in the floor of the third ventricle, the capacity to regulate body temperature is lost. When the normal individual is hot, vasodilatation permits the loss of excess heat by radiation, whereas in the cold vasoconstriction prevents this. In states of emotional excitement the sympathetic nerves likewise constrict the superficial vessels and one develops "cold feet," literally as well as figuratively. With this discharge the sympathetic nerves, which are very indiscriminating in their action, activate the sweat glands as well. We all know among our acquaintances individuals with cold, clammy hands. Cobb,⁶ who has been making a special study at the Massachusetts General Hospital of the personality that goes with this type of sympathetic imbalance, finding that these individuals have a special psychological makeup which is perhaps characterized by inner emotional turmoil thoroughly covered and repressed beneath an outwardly normal appearance and behavior.

For my own part, I have become more and more impressed that this syndrome constitutes a true constitutional inferiority. These individuals are likely to develop scleroderma and arthritis, if they are victims of infantile paralysis, their cold legs are likely to stop growing and to ulcerate. In most of the cases of causalgia and amputation stump neuralgia this type of circulation exists, and it was present preceding the injury. I believe that a low pain threshold, as well as a personality that is poorly equipped to fight life's battles usually accompanies this syndrome. This is a personal impression.

What is more likely to impress the average practitioner are the more severe degrees of the disorder. These are commonly classified as Raynaud's disease, if there are symmetrical phases of digital blanching and cyanosis, or as acrocyanosis when the extremities are constantly blue as well as moist and cold. At the onset the vascular walls are normal, but Sir Thomas Lewis has shown that the constant asphyxia which accompanies the severer forms of these disorders may lead to an early endarteritis. A number of very satisfactory tests have been devised to pick out the cases favorable for operative interruption of the vasoconstrictor nerves. These consist either of getting the body in the hot vasodilated state by fever from typhoid vaccine or by heating, or of paralyzing the vasoconstrictor nerves by an anesthetic. Patients who have vasoconstrictor disorders of sufficient severity to result in chronic vasospasm in a room at 70° F. should be submitted to sympathectomy before endarteritic changes appear in their digital arterioles, and before a constricting bed of scar tissue replaces the subcutaneous tissue.

OPERATIVE RESULTS

To go from the simple to the more complex, the results of cutting the vasoconstrictor nerves to the lower extremity have been uniformly satisfactory. To do this the second and third lumbar sympathetic ganglia have been resected. As Raynaud's disease is far less frequently severe in the feet than in the hands my colleagues and I have operated on only eighteen patients for this condition in the legs. All these opera-

tions have been successful and free from any major complications. The results up to six years after operation are as satisfactory as on the day of discharge.

In the arm, however, the results have been far less successful. All together Dr. Smithwick and I have performed fifty-eight sympathetic ganglionectomies on thirty-eight patients. Our experiences are best summarized by dividing them into three groups. In the first, only the upper two thoracic ganglions were resected. In the second, the extent of this operation was increased to include the inferior cervical ganglion. In our third and present series, a new form of sympathetomy has been employed which I am going to describe in some detail. In the first series of ten cases, removing only the first and second thoracic ganglions proved to be an inadequate operation. The early results were good, but in six the vasodilatation lasted only six months and then there was a complete recurrence. The reappearance of sweating showed that the cause of failure here lay in the reestablishment of nervous connections.

In the second series we carried out the final modification of Adson's⁸ operation, taking great care to resect the inferior cervical and the first and second thoracic ganglions in their entirety. After this has been done the sweat glands are permanently paralyzed, but the hand remains fully dilated for only a fortnight. Theoretically it seemed as though the hand in an early favorable case should have remained as permanently dilated as the foot. Yet it was a most tantalizing fact that it did not. In a series of eleven of these patients we constantly observed a partial recurrence of vasospasm beginning about a fortnight after cervicothoracic ganglionectomy. Lewis and Landis⁹ have called attention to this, and most of the surgeons who have had a large experience with the operation in this country have been similarly impressed. In our series of cases the recurrence of vasospasm completely vitiated the early post-operative improvement in four patients and caused us to classify the others as only mediocre results.

This is best illustrated by a typical patient who has had both her upper and lower extremities denervated. On examination two years after her operations in a room at 70 F., her feet remain as warm (90 F.) and free from color changes as on the day of her discharge from the hospital. Her hands, on the contrary, although free from perspiration, may become cyanotic on exposure to cold or nervous excitement and their surface temperature averages from 75 to 78. This is better than before her cervicothoracic ganglionectomy, but the result leaves much to be desired.

In 1933 the recurrent attacks of cyanosis in the hands of a patient two weeks after a complete cervicothoracic ganglionectomy led Dr. Smithwick and me to call a halt on the upper extremity operation until we could discover the mechanism of this recurrent form of spasm. It was quite obviously not neurogenic because after these patients had been heated to the point of generalized sweating the denervated hands remained perfectly dry. As the nerve supply to the sweat glands is the same as that to the blood vessels, this test showed that the vasoconstrictor nerves were interrupted. The clue to this impasse was given us by Dr. Norman Freeman, who had worked in Dr. Cannon's laboratory and told us of the fact long known to physiologists, that denervated smooth muscle remains sensitive to the circulating sympathomimetic hormones epinephrine and sympathin. Not only does smooth muscle remain sensitive, but it becomes hypersensitive.

We promptly tested all our available cases and found that physiologic doses of epinephrine or adrenal secretion stimulated by excitement or by insulin hypoglycemia were promptly followed by a striking fall in surface temperature and all the signs of vasospasm.¹⁰ With Okelberry and Whitelaw¹¹ I have studied this phenomenon in the rabbit's ear and the monkey's hand. We discovered that the blood vessels in the rabbit's ear become so sensitive to epinephrine within a week after superior cervical ganglionectomy that they constrict to a maximum whenever the animal is cold, struggles or becomes excited. A lasting vasodilatation can be obtained only when adrenal secretion is abolished.

These observations did not explain the differences observed after sympathetic denervation of the human arm and leg. But it soon became apparent that this difference depends on whether the preganglionic or the postganglionic vasoconstrictor neurons are cut. This anatomic variation in epinephrine sensitization was clearly demonstrated by Hampel.¹² Wherever the vasoconstrictor pathway is interrupted there is some degree of adrenal sensitization, but from a quantitative point of view it is roughly true that this is only a third as great if only central fibers are cut. Our observations have been fully corroborated by Grant¹³ and by Telford.¹⁴ In lumbar ganglionectomy the postganglionic fibers to the sciatic nerve which arise in the last lumbar and the sacral ganglions, are preserved. Smithwick¹⁵ and also Telford¹⁴ have devised an operative technic for sparing these fibers to the brachial plexus and cutting only the preganglionic fibers to the arm. This can be accomplished by leaving the inferior cervical, first and second thoracic ganglions in situ, but cutting the sympathetic chain below its third thoracic ganglion and severing the communicant rami from the second and third intercostal nerves. This operation has now been performed twenty-eight times on eighteen patients at the Massachusetts General Hospital. Observations over a period of one and one-half years have demonstrated that the lasting increase of blood flow in the arm after this operation can be as great as in the leg.

CONDITIONS OTHER THAN RAYNAUD'S DISEASE

Operations for the relief of chronic vasospasm are of great value in a number of conditions aside from true Raynaud's disease.

1. In scleroderma and sclerodactyly improvement of circulation has been followed by an arrest in the

advance of the disease and by an improvement in function of the hand. We have had satisfactory results in four cases. As these conditions commonly involve the hands, the results of the new operation of preganglionic neurectomy should be even more impressive. In the advanced forms of the disease, however, in which the vessels are compressed in a bed of scar tissue, no improvement can be expected. We have had three failures in this group.

2 In the late stages of poliomyelitis increasing the circulation of the paralyzed leg may be of value for two conditions: for trophic lesions and for increasing bone growth in the legs (Harris¹⁶). It is important to point out that no permanent increase in blood flow can be expected in a totally paralyzed leg.

3 In 1927 Rowntree and Adson¹⁷ advocated sympathetic ganglionectomy for increasing circulation to the affected joints in certain selected cases of rheumatoid arthritis. They postulated that the operation must be limited to young individuals with superimposed vasospasm and with a good vasomotor index. Furthermore, the operation was applicable only when the hand or foot was involved, as there is little increase in circulation above the elbow or knee. Few favorable reports have appeared from other clinics, and in five cases observed with Dr. Walter Bauer of the Robert W. Lovett Memorial Foundation for the Study of Joint Disease we have been unable to obtain any increase in joint mobility or relief of joint pain. I can recommend this operation only in the rheumatoid type of arthritis when it is desirable to improve circulation per se in the cold, moist extremities.

In cases of traumatic arthritis the story is quite different. In this condition there is often an accompanying osteoporosis and vasomotor disturbance. This reflex atrophy of bone which Sudeck first described, may follow minor fractures or trauma near the wrist or ankle. It is sometimes intractable to ordinary orthopedic measures and has then cleared up after restoration of an adequate circulation. Even a temporary hyperemia, such as follows procaine injection of the sympathetic ganglions or periarterial sympathectomy, has sufficed to start active use of the crippled extremity and resulted in complete relief. We have found procaine block to be sufficient in two cases. Fontaine and Herrmann,¹⁸ who have reported twenty-two cases, believe that ganglionectomy should be reserved for the severest forms. Our knowledge here is still very incomplete, both as to the physiology of painful bone atrophy and as to why sympathectomy works so well at times and then occasionally fails.

4 Hyperhidrosis or excessive sweating of the hands may be a very disagreeable condition. Under these circumstances the fingers and palms may actually drip with perspiration especially under nervous excitement. This can be stopped by sympathectomy. We have had two recent cases: the first in one of our stenographers who was constantly smearing her typing. She has been relieved for four years by resection of the first and second thoracic ganglions. In a second case, a medical student felt that surgery would be impossible for him to undertake on account of the excessive moisture of

his hands, I blocked the corresponding ganglions by paravertebral alcohol injection. By this method he needed hospitalization for only one night and returned to his classes the next day. At the end of two years he maintains normally dry hands.

5 In thrombo-angitis obliterans, when endarteritis has occluded the main arteries, vasospasm may contract the all important collateral vessels. The natural physiologic response to pain is vasoconstriction. Certain clinics have recommended lumbar ganglionectomy whenever there is a favorable vasomotor index. The Peripheral Vascular Clinic at the Massachusetts General Hospital has never subscribed completely to this view. In the first place, lumbar ganglionectomy cannot be expected to relieve the pain of gangrenous toes. A much simpler procedure, crushing the peripheral nerves,¹⁹ can be carried out under local anesthesia without even putting the patient to bed. This operation relieves all pain and produces a complete, although temporary, paralysis of the vasoconstrictor nerves. After a wave of acute thrombosis in Buerger's disease, interruption of nerve conduction for three months is usually sufficient to enable the patient to pick up an adequate collateral circulation. In a series of more than twenty-five severe cases during the last six years, the necessity for major amputation has been reduced 60 per cent by the use of this simple and minor operative procedure. It is therefore logical to crush the peripheral nerves in all severe cases with actual gangrene and pain. Lumbar ganglionectomy should be reserved for those rare instances of Buerger's disease in which, after the paralyzed peripheral nerves have regenerated, vasospasm again becomes a complicating factor. When used in this way, lumbar ganglionectomy is a most valuable procedure. We have needed to do this in only twelve cases.

6 In discussing the recently proposed forms of sympathectomy for lowering blood pressure in essential hypertension, many interesting problems must be considered. Let me first review a few of the important physiologic facts that are known about the mechanism of the hypertensive state. These have been very ably presented by Dr. Soma Weiss.²⁰

In the first place, vasomotor tonus in hypertension is perfectly normal and is superimposed on an intrinsic arteriolar spasm. This last factor is not neurogenic in origin, nor is it due to circulating chemical substances such as an excess of epinephrine. The elevations of diastolic and systolic pressures are secondary manifestations and must be looked on as compensatory homeostatic adjustments for the maintenance of an adequate capillary circulation in the tissues. The exact nature of the change in the arterioles and arteries is unknown. Prinzmetal and Wilson²¹ have shown that the increased vascular resistance is not confined to the splanchnic area but is generalized throughout the systemic circulation. Sympathetic vasodilatation in an extremity produced by the 'heat' test or by paralysis under procaine infiltration of the sympathetic ganglions produces no greater increase in blood flow in hypertensive than in normal individuals. If the vascular spasm of the hyper-

tensive were due to an excessive activity of the sympathetic nervous system, the rationale for sympathectomy would be clear. Unfortunately, this is not the case. In addition, it is known that total extirpation of the sympathetic nervous system in animals produces no lasting fall in blood pressure.

To take up the other side of the picture, the fact that extensive sympathectomy produces no striking fall in the blood pressure of the normal dog and cat does not necessarily mean that it cannot reduce the blood pressure of a hypertensive human being. Clinical evidence to date has given a rather definite contradiction of the theoretical objections.

It is now well recognized that hypertensive individuals show abnormal pressor responses to cold and emotion. Clinical evidence reported by Adson, Craig and Brown,²² by Page and Heuer²³ and by Peet²⁴ constitute fairly convincing proof that sympathectomy can cause a worth while reduction in blood pressure in certain favorable cases of essential and malignant hypertension. When it is considered that this condition usually progresses to a fatal termination, surgical attempts at its amelioration are certainly justifiable, provided medical treatment has been tried and found to be ineffective.

The proposed surgical methods fall into three main categories.

1 Operations to reduce adrenal secretion, either by partial adrenalectomy or by adrenal denervation. Such procedures should be condemned first because they are inadequate and secondly because they may be followed by Addison's disease. Such a case has recently been reported by Rogoff,²⁵ and I have seen a second.

2 Cutting the lower six thoracic and upper two lumbar anterior spinal roots, which has been recommended by Adson, Craig and Brown.²² This radical operation interrupts the vasomotor outflow to the lower half of the body, as well as the nerves to the adrenal glands. I have had no personal experience with this method, but in the hands of Adson and of Heuer²³ it has been followed by a considerable number of striking results.

3 Splanchnicectomy. This operation interrupts the secretory fibers to the adrenal glands and vasoconstrictor fibers to the splanchnic area. It can be carried out either above or below the diaphragm. The intra-thoracic approach, devised by Peet,²⁴ cuts these fibers with greater certainty and over a larger extent. It has now been used at the Massachusetts General Hospital by Dr. Smithwick in twelve cases. The results of this operation to date appear to be nearly as good as those of the more radical and far more mutilating method of ventral root section.

To summarize the results of these operations, it seems fair to state that they show signs of promise in early favorable instances of hypertension. Even after the most careful selection some of these cases are likely to fail; the operations are difficult and the mortality rate is fairly high. For the practitioner who primarily cares for the patient this is important to appreciate. Investigation has to progress through justified and intelligent trial and error. It is wise that physicians

should accept new surgical procedures only after proper evaluation of the problem and strong supporting evidence. In the problem of hypertension, this stage cannot be said to have been reached. At present, therefore, it seems advisable to leave the operative treatment of hypertension in the hands of those who are best qualified to perform this difficult type of surgery and who can be trusted to observe their operative results with open minds and so decide whether there is lasting benefit to their patients.

CONCLUSION

I have centered my remarks on the physiology and surgery of the vasomotor nerves. I have done this purposely because it is the line that is advancing most rapidly today. An equally important matter, the relief of visceral pain, is too large a subject to cover and does not, strictly speaking, belong in the field of the sympathetic nervous system. I have not taken up the application of sympathectomy to several important conditions, because these are not related to abnormal reactions of the blood vessels. The most outstanding of these is sympathectomy in the treatment of megacolon. All who have used this operation agree that it is consistently effective in suitable cases of Hirschsprung's disease. On the other hand, presacral neurectomy is not a sound method for improving the function of a paralyzed bladder. This has been shown both by disappointing clinical results and by the recent work on the physiology of micturition. I have said nothing about the application of sympathectomy to spastic paralysis because it is now conceded that this operation is totally illogical.

A great many unphysiologic procedures have been advocated in the past, but in their justification it must not be forgotten that this entire field of neurosurgery has developed out of Royle and Hunter's suggestion for the treatment of spastic paralysis. This method and many others were based on inadequate fundamental knowledge, advocated with too great enthusiasm and then thrown into the discard. Surgical intervention on the sympathetic nervous system is just emerging from the stage of trial and error. This is due not only to an accumulation of clinical experience but equally to a better understanding of the function of the visceral nerves and a development of diagnostic tests. Of the subjects which I have discussed in this paper, the operative treatment of hypertension alone appears to remain in question. The real value of the others now rests on a firm foundation.

Massachusetts General Hospital

Bacteria in the Stratosphere—Specimens of bacteria floating in the stratosphere between 36,000 and 70,000 feet were obtained and identified. In all there were ten colonies collected and of these, five proved to be aerobic, spore-forming bacilli while the other five were mold fungi identified as *Rhizopus* sp. *Aspergillus niger*, *Aspergillus fumigatus*, *Penicillium cyclopium* and *Macrosporium tenuis*. Not only are these organisms of importance to man but it may be assumed that numberless other pathogenic organisms of similar size and weight are floating high in the air. A study of the influence of the prevailing wind directions and the occurrence of rising and falling columns of air on the origin and spread of endemic or epidemic diseases would no doubt be of inestimable value. Also in this connection the transfer of disease germs by means of aircraft must be borne in mind.—Armstrong, H. G. The Medical Aspects of the National Geographic Society-U. S. Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT

HOWARD A. CARTER Secretary

BURDICK SUCTION-PRESSURE UNIT ACCEPTABLE

Manufacturer The Burdick Corporation, Milton, Wis

This unit is recommended by the firm for the administration of suction-pressure therapy, particularly in the treatment of peripheral vascular disease. It consists essentially of a pump for creating positive and negative pressures, a motor, and a

Burdick Suction Pressure Unit

boot or chamber in which the extremity is inserted for treatment. The combined weight for shipment is 550 pounds. About 300 to 400 watts of electrical energy is required.

The two-cylinder pump is driven by a one-half horse power motor. Either alternating or direct current may be used as a source of power. The power plant is housed in a steel cabinet on top of which are located the

controls. By the aid of a selection of cams, either the suction or the pressure period may be changed. From one to four boots may be run at the same time. The boots are made of aluminum, with windows of cellulose acetate. The weight of one boot is 35 pounds and the length is 28 inches. The manometer is placed on the boot and its readings check closely with mercury manometers connected with the pressure chamber. A safety vacuum valve is a part of each boot, eliminating the danger of applying excessive vacuum pressures. Molded, stiff cuffs are furnished in three different sizes. Six soft, sponge rubber adapters, which may be inserted in the cuffs, are available to accommodate the intermediate or small size thigh or arm.

This machine was examined in a clinic acceptable to the Council. It was operated under actual conditions and its performance appeared to be in accord with the claims made for it. Pressures between -80 and -20 mm of mercury may be obtained.

Some indications for the use of this type of apparatus appear to be acute vascular occlusion, freezing, and vascular diseases with major involvement of the large vessels. Contraindications appear to be thrombophlebitis, cellulitis or lymphangitis (acute or subacute), extensive destruction of the arteriolar or capillary vessels, advanced thromboangitis obliterans with capillary stasis, and advanced arteriosclerosis with capillary stasis and venous thrombosis.

This apparatus has a very limited field of usefulness and probably therefore does not belong in the armamentarium of the average physician. It belongs more in the realm of hospital equipment, since most of these rare arterial diseases are hospital cases.

In view of the satisfactory performance of this unit with reference to the treatment of acute vascular occlusion, freezing and vascular diseases with major involvement of the large vessels the Council on Physical Therapy voted to include the Burdick Suction-Pressure Unit in its list of accepted devices.

DRINKER INFANT RESPIRATOR ACCEPTABLE

Manufacturer Warren E. Collins, Inc., Boston

The Drinker Infant Respirator is an apparatus for producing and maintaining artificial respiration in infants. It consists mainly of a chamber of suitable size to accommodate an infant. Insulated heating elements are provided for maintaining body temperature. When in operation, it is entirely closed except for the opening through which the infant's head protrudes. The pump which creates a vacuum and a slight pressure is operated by a motor and alternately exhausts the air from and returns it to the chamber. The negative pressure causes an expansion of the chest walls of the infant, permitting atmospheric air to enter the nostrils and mouth and hence into the

lungs. The products of respiration are exhaled when the vacuum is released in the chamber and the chest walls contract. Thus a moderate degree of measured negative pressure alternating rhythmically with positive pressure is maintained for a long period. The device is equipped with a heating element enabling it to be used as an incubator. A constant temperature is readily produced and easily maintained, and the rate and depth of breathing may be adjusted.

The machine was carefully investigated in twelve cases in a clinic acceptable to the Council. Included in this series were cases of simple apnea, several cases of asphyxia livida, one premature infant and one baby having asphyxia pallida. All the infants survived and were discharged from the hospital in satisfactory condition.

Preparation for mechanically induced artificial respiration consisted in cleaning the infant's air passages of any obstructing material. This was effected in the most gentle manner. In one case a soft tracheal catheter was left in the trachea during the operation of the machine. At times oxygen or carbon dioxide and oxygen were also used in association with the respirator. Both negative and positive pressures, rather than just the negative pressure, were employed, the two at the same pressure. This pressure varied from 25 to 45 respirations per minute. The slower rate seemed better.

Three principles govern the treatment of those infants needing aid: (1) clearance of the air passages, (2) maintenance of body heat, and (3) provision of a supply of oxygen to the blood. After removing obstruction, artificial inflation and deflation of the lungs and a tracheal catheter are used very infrequently.

The respirator is a valuable adjunct when efforts at resuscitation must be persisted in for a long time. Apparently, some patients have completely recovered after four hours of mouth to lung insufflation, combined with manual artificial respiration. The apparatus would save much time and energy. It seems valuable with premature and immature infants, and in babies who have breathed irregularly and with shallow inspirations, it apparently stimulates deeper, more frequent and regular respirations. In a previously, absolutely nonaerated lung it is questionable whether the apparatus can produce any great degree of alveolar expansion. It will not initiate natural respiration.

The Council believes the danger of the production of emphysema and pneumothorax from rupture of the alveoli during mechanical artificial respiration to be slight, but nevertheless possible. As far as can be determined from the Council's investigation, the apparatus probably should not be used in infants having intracranial injury and hemorrhage. These conditions might conceivably be aggravated by the forced action of the respirator.

In view of its favorable performance, the Council on Physical Therapy voted to include the Drinker Infant Respirator in its list of accepted devices.

Drinker Infant Respirator

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT

PAUL NICHOLAS LEECH Secretary

STATUS OF PICROTOXIN

Report of the Council on Pharmacy and Chemistry

Picrotoxin which is an extremely active poison, has long been proposed for use in a variety of conditions, including poisoning with chloral hydrate but a wide experience has always resulted in its falling into practical disuse. As long ago as 1909 it was proposed for inclusion in New and Nonofficial Remedies as useful in the treatment of tuberculosis and in epilepsy. The Council refused recognition because of the likelihood that the drug would do more harm than good.

Calling attention to the recent work of Maloney and others indicating that picrotoxin may have a certain value in com-

bating the acute toxic effects arising from overdosage with barbitol and its derivatives, Eli Lilly & Company asked the Council to consider Ampoules Picrotoxin (Lilly) for admission to New and Nonofficial Remedies as an agent for use in this condition. The firm stated "It will be emphasized that the clinical use of picrotoxin is still in the experimental stage and that Ampoules Picrotoxin are made available solely to facilitate further investigation." It was pointed out to the firm that such investigation should be carried out by workers in hospitals or other institutions equipped for scientific work and not by the general practitioner.

The Council's referee called attention to the clinical report of Arnett (*THE JOURNAL*, May 20, 1933, p 1593), pointing out that it presents so many unknown factors as to be of no value beyond that of being suggestive of the possible value of picrotoxin in the treatment of barbitol poisoning if indeed it is that since Arnett used various measures and there is no evidence that his patient took a fatal dose of Amytal, certainly not that a fatal dose had been absorbed before the stomach was emptied. The referee also pointed out that wide differences in effectiveness had been found by Maloney in the use of picrotoxin against different barbiturates—negligible, for instance, against phenobarbital and many times greater against Nostal. Much more should be known about this antagonism before the Council could be justified in accepting Picrotoxin for distribution to the general practitioner.

The Council does not wish to imply a belief that picrotoxin is of no value in the treatment of barbitol poisoning. It awaits the development of further evidence in the work of competent investigators. The Council is, however, convinced that the evidence now available for this use does not justify the placing of a marketed product in the hands of the general practitioner irrespective of his facilities for using it with the greatest benefit to his patient, for determining its therapeutic value and contributing the evidence in a satisfactory way.

When Eli Lilly & Company was informed of the Council's attitude in the matter of offering picrotoxin to the general practitioner, the firm announced its intention of withdrawing its Picrotoxin Ampoules from the market.

The Council desires to express its appreciation of this enlightened action on the part of the firm and to voice the hope that other manufacturers of pharmaceuticals will refrain from making picrotoxin generally available until competent investigators have cleared up the questions of its safety and clinical effectiveness, especially in the treatment of acute poisoning from barbitol derivatives.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

ANAEROBIC ANTITOXIN (See New and Nonofficial Remedies, 1935, p 366)

E. R. Squibb & Sons, New York, N. Y.

Gas Gangrene Antitoxin—Prepared from the serum of horses which have been immunized against the toxins of *Cl. Welchii* (perfringens) and *Cl. oedematis maligni* (vibrio septique). After the desired degree of potency is obtained the horses are bled the plasma is separated and the serum prepared in a manner similar to that used for other antitoxic sera. The product is concentrated and refined by a method which is similar to that used for diphtheria antitoxin. As a preservative 0.5 per cent phenol is added. Marketed in packages of one vial containing 10 000 units of *Clostridium Welchii* antitoxin and 10 000 units of *Clostridium oedematis maligni* antitoxin.

Dosage—The contents of one vial or more injected intravenously intramuscularly or intraperitoneally, at intervals of twenty-four to forty-eight hours, according to the requirements of the individual case.

Tetanus-Gas Gangrene Antitoxin—Prepared from the serum of horses which have been immunized against the toxins of *Cl. tetani* (tetanus), *Cl. Welchii* (perfringens) and *Cl. oedematis maligni* (vibrio septique). After the desired degree of potency is obtained the horses are bled the plasma separated and the serum prepared in a manner similar to that used for other antitoxic sera. The product is concentrated and refined by a method which is similar to that used for diphtheria antitoxin. As a preservative, 0.5 per cent phenol is added. Marketed in packages of one syringe containing 1 500 units of *Clostridium tetani* antitoxin 2 000 units of *Clostridium Welchii* antitoxin and 2 000 units of *Clostridium oedematis maligni* antitoxin.

Dosage—The contents of one syringe injected subcutaneously or intramuscularly as promptly as possible after injury and repeated once or twice at seven-day intervals if further danger of infection is present.

Council on Foods

CHANGE IN NAME OF COMMITTEE ON FOODS TO COUNCIL ON FOODS

On the recommendation of the Committee on Policy, Rules and Procedure (representing the Council on Pharmacy and Chemistry, the Council on Physical Therapy and the Committee on Foods) the Committee voted that it would be advantageous to change the name "Committee on Foods" to "Council on Foods." The name "Council" gives to this group a title uniform with that established by the Association for similar bodies. The Committee transmitted this recommendation to the Board of Trustees. The Board, at the Kansas City meeting, ratified the change, which took effect July 1, 1936.

Old seal

New seal

The seal of the Council on Foods is identical with the older seal of the Committee except for the change in name. New typographic plates have been prepared and may be secured from the Association headquarters. All possible consideration will be given cooperating firms to make the change in the seal, and for a reasonable time they will be permitted to continue to use the acceptable labels and advertising bearing the old seal of the Committee on Foods.

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REVISED WORDING OF ITS EARLIER DECISION ON ENERGY CLAIMS

FRANKLIN C. BING, Secretary

ENERGY CLAIMS FOR FOODS

All foods except the simple mineral foods and water contain chemical energy available for use by the healthy body to support the many activities and life processes and incidentally to maintain temperature. This use of the term "energy" in defining the caloric energy value of foods should not be confused with the popular usage signifying activity, vitality, strength, vigor or endurance. These conditions depend on many factors, including freedom from disease, natural constitution, physical environment, training, habits and others. Good nutritive condition, a necessity for health, requires far more than food energy only, all the nutritional essentials of a complete, well balanced diet, in adequate amounts, are demanded.

Food advertising should correctly inform the public of the energy values of foods in carefully chosen terms that may be properly interpreted. The distinction between the caloric and popular senses of the word "energy" must be recognized and observed.

The advertisers of food products should also take cognizance of the fact that limitation of the energy intake is essential for reduction of body weight. There are no foods that burn up body fat. This is burned only when the total energy intake is reduced to a point at which the body is forced to draw on its own stores for fuel. Furthermore the time of the day when food is eaten has nothing to do with the production of body fat. Regardless of the number of meals eaten, the total energy value of the day's food intake will determine whether the diet is fattening or reducing.

The expression 'Provides energy' or 'Furnishes energy' is acceptable when it is clearly indicated by appropriate modifying phrases that 'food energy' or 'calories' is meant. In general, ordinary foods except water and salt are sources of energy. Statements of calories per unit weight are useful as indicating relative economy of different foods as sources of energy, but for healthy persons calories from one food are not to be regarded as of more value than those from any other food.

SATURDAY, AUGUST 1, 1936

ORIGIN OF BENCE JONES PROTEIN

Bence Jones protein is an albuminous substance which appears in the urine under certain pathologic conditions. The material is characterized by precipitation at a relatively low temperature (from 40 to 50 C) and resolution as the temperature of the medium approaches the boiling point. The presence of this protein in the urine has been of clinical aid in the diagnosis of multiple myeloma. This protein material escapes catabolism and passes the kidneys in amounts so great that the nitrogen excreted in this form may amount to a third or more of the total nitrogen excreted.

Although it is a highly complex substance forming colloidal solutions, it may be passed in large quantities for long periods by kidneys which remain impervious to plasma proteins and which are, to all appearances at least, histologically intact. The question of the origin of Bence Jones protein is of particular interest. Is the protein of endogenous or of exogenous origin? Is it derived from the serum proteins? Is Bence Jones protein present in the normal organism, in the normal bone marrow, or does it arise as a manifestation of an alteration of the normal processes of protein metabolism?

The chemistry of Bence Jones protein has been rather carefully investigated as a means of approach to the problem of its origin. An estimated molecular weight of 35,000 for the substance strongly suggests that this material might well be a product of the cleavage of blood proteins or identical, perhaps, with serum albumin. This view is supported by similarities in amino acid composition between the serum proteins and Bence Jones protein. However, immunologic studies that have been conducted on purified Bence Jones protein indicate that it is a distinct chemical entity apart from the serum proteins. Precipitin, complement fixation and anaphylactic reactions establish crystalline Bence Jones protein to be a single antigen, distinct from the proteins of normal human serum.

Impure preparations of the protein may occasionally react immunologically as though they contained traces of serum proteins.

The rather conclusive nature of the evidence indicating the nonidentity of Bence Jones protein with blood proteins has led investigators to study the most probable site of origin of the material, the bone marrow. It was early possible to demonstrate the presence of a Bence Jones-like protein in myelomatous tissue. Only recently, however, has this protein been demonstrated in normal bone marrow. Meyler,¹ working in the Netherlands, has succeeded in obtaining extracts of both calf's bone marrow and the bone marrow of normal man and has demonstrated that the extracts contain a protein that has properties identical with those assigned to Bence Jones protein. The behavior of the extract toward heat, and variations in this heat reaction by alterations in electrolyte concentration of the protein solution, were characteristic of Bence Jones protein. Furthermore, it was possible to produce an experimental Bence Jones proteinuria in rabbits by the injection of the bone marrow extract. This observation is in harmony with earlier reports that injected Bence Jones protein is excreted to a considerable extent unchanged following injection into an experimental animal. The author presents some evidence which indicates that the Bence Jones protein is produced in normal bone marrow as part of the lymphocytes and other leukocytes. This would explain the presence of Bence Jones proteinuria not only in cases of multiple myeloma but also in reported instances of lymphatic and myeloid leukemia and empyema, as the white corpuscles are the substrate common to these diseases. Meyler has succeeded in detecting Bence Jones protein in the pus of abscesses and empyema, and also in the lymphocytes and other leukocytes in cases of leukemia. Injection of an extract of lymphocytes from a patient with lymphatic leukemia into a rabbit produced Bence Jones proteinuria in the animal. The differences in the degree of proteinuria in cases of multiple myeloma as contrasted with leukemia and empyema are explained on the basis of the quantity of Bence Jones protein produced by the white cells. When bone marrow is broken off (in cases of tumor metastasis) or when the white cells are destroyed (in leukemia and empyema), Bence Jones proteinuria does not appear, as a rule, as the quantity of the protein produced is relatively small. In cases of multiple myeloma, however, the white cell may have the power to produce a large quantity of Bence Jones protein, not all of which can be metabolized, the excess is consequently excreted in part by the kidney. This investigation offers an interesting suggestion concerning the origin of Bence Jones protein and has correlated many of the existing clinical facts regarding this type of proteinuria.

FACTORS AFFECTING BASAL
METABOLISM

Factors such as age, diet, climate, race and menstruation exert a significant effect on the basal metabolism of the normal human subject. Each of these has received considerable attention, particularly the questions of age and of diet. The effect of age has been adequately established. There is a steady increase during infancy from the low values of approximately 25 calories an hour per square meter of body surface obtained on new-born infants to a maximum value somewhat greater than 50 calories an hour per square meter of body surface at an age of between 3 and 5 years. Thereafter a gradual decrease in basal metabolism occurs during childhood, middle age and old age. The exceedingly low value of 21.1 calories an hour per square meter of body surface has recently been obtained¹ in a woman 106 years old.

The decrease in basal metabolism during childhood is constant with the exception of a temporary rise that has been frequently described in both boys and girls at about the age of puberty. The reason for the pubertal rise is not known with certainty, some believe that it may be associated with hyperactivity of the thyroid gland at this period, others believe that it may be related to the increased rate of growth frequently occurring in the adolescent. A recent study² yields some information regarding the latter view. Periodic determinations of the basal metabolism were made in a group of thirty-nine growing, adolescent girls ranging in age from 14 to 16 years, chosen so that puberty itself was not a conflicting factor. The metabolism data were then related to age, rate of growth in stature and time since menstruation first occurred. The data thus obtained showed that the basal heat production, expressed either as calories for twenty-four hours, calories per kilogram of body weight for twenty-four hours, or calories per square meter of body surface for twenty-four hours, decreased slightly but consistently with age. There were no constant trends or regular differences between the values, however, when they were classified either according to time since the first menstruation, the age of the first menstruation, or the age of maximum increment of growth in stature. Thus there is no indication in these data of a relation between the rate of adolescent growth and basal metabolism. Other factors must be concerned in producing the frequently observed transient rise in basal heat production observed at puberty.

The nature of the diet may also exert a profound influence on the basal metabolism of the normal human subject. The basal metabolic rate of strict vegetarians, for example, is consistently some 11 per cent lower than that of persons consuming an ordinary unrestricted diet.³ A similar lowered rate of metabolism has been

repeatedly observed in those receiving a submaintenance diet. The decrease in basal metabolism in undernutrition might lead to the belief that a rise would occur in "overnutrition." Indeed, many have long believed that overnourishment is accompanied by a "luxus konsumption," or a luxury consumption of energy. According to this view an excess of nourishment would be burned up and not stored in the body. The more recent work indicates that the attractive theory of "luxus konsumption" is still not adequately demonstrated.

A current investigation⁴ adds further interesting information regarding the effect of dietary intake on basal metabolism. The study was made on a group of thirty-three healthy children whose ages ranged from 4 to 15 years and in whom it was possible to control the diet at will. The effect on basal metabolism of both undernutrition and overnutrition due to the excessive eating of carbohydrate, fat or protein was determined. The feeding of a submaintenance diet was followed by the expected decrease in the basal heat production. The addition to an adequate diet of excessive amounts of either carbohydrate or fat caused little if any significant change in basal metabolism. However, the feeding of large quantities of protein was followed by an increase in basal heat production. These results indicate that overnutrition due to carbohydrate or fat causes no significant elevation in basal metabolism, whereas excessive amounts of protein produce a distinct increase, at least in the growing child. This observation adds further to the evidence attaching special significance to the protein content of the diet as a factor affecting the basal heat production.

NEW METHODS OF SCIENTIFIC PUBLICATION AND BIBLIOGRAPHY

The dissemination of new scientific knowledge is second in importance only to research itself. The results of research cannot be of full value in the advancement of science unless they are made known. Publication is the first step in the dissemination of knowledge, the next step is the incorporation of published matter into the bibliography of the subject with which it deals. At present scientific journals cannot always publish all the worthy material offered and in many cases *more prompt publication than now possible* may be desirable, also in certain branches of science the *bibliographic services are inadequate* and may become more so. Fortunately the last statement does not apply to medicine, because the bibliography of the older literature is well covered by the *Index Catalogue* and that of the current literature by the *Quarterly Cumulative Index Medicus*, published by the American Medical Association. A comprehensive and ambitious plan to improve and expand the facilities for scientific publication and bibliography has been inaugurated by Science Service. The new enterprise will center in the

Documentation Division of Science Service, for the work of which the Chemical Foundation has given a grant of \$15,000.¹ Documentation has been defined in the broad sense as "the assembling, classification and distribution of documents of all sorts in all fields of human activity." By way of enlarging the facilities for scientific publication the Documentation Division has developed photographic mechanisms for the prompt issuance of papers and monographs that existing periodicals in various branches of science cannot publish promptly if at all. The plans are based on cooperation with existing periodicals societies and institutions. Microfilms are made of manuscripts, from which prints can be produced for reading in special machines as well as projection prints for direct reading and general distribution. The films will be permanent and, as orders can be filled as received, no storage of printed stock will be necessary. The process just outlined is used also for copying printed and other matter at small expense. The process is already in use in certain libraries for research purposes and in place of inter-library loans. Thus the Bibliofilm Service of the U. S. Department of Agriculture is said to give excellent results. Eventually it may prove practicable and economical to publish certain periodicals by microphotographic methods. It is possible to reproduce by microphotography say 150 or more pages of ordinary typescript on an area 3 by 5 inches in extent, from such negatives, prints can be made for reading machines as well as for direct reading. Special attention is given to the development of these methods in cooperation with Dr. R. H. Drager of the medical corps of the navy. The outlook promises well for the development of new and helpful methods of reproducing reading matter on a large scale. It will be of interest to learn how the problem will be solved of reproducing illustrations, which are such an important feature in medical and other biologic literature.

Science Service is interested also in scientific bibliography. It dreams of a complete, centralized international bibliography, of a master file of cards punched and marked to actuate an assorting mechanism to which is linked a duplicating machine from which bibliographic lists can be delivered instantly to order as desired. Assuming the scheme to be practical, what shall be done with past and present bibliographies? No attempt will be made to discuss details at this time, but the following statement of proposed bibliographic investigations may be of interest: the extent and adequacy of the bibliographies of the scientific literatures of the past, current bibliographic services and the possibility of their cooperation in new plans, the methods of classification, bibliographic mechanisms (including devices for filing and finding, microphotographic cameras, printers) the problems of language and copy-

rights, methods of international cooperation. Here is a huge task and "the possible inauguration of the bibliographic project is a matter of years and considerable expenditure of money."

Current Comment

END RESULTS OF DIAGNOSIS OF NEUROSIS

The term neurosis is still frequently applied purely as a diagnosis of exclusion. The adequacy of this method is, however, open to serious question. In an attempt to throw more light on this problem, Comroe¹ has recently reported a follow-up study of 250 cases diagnosed as neurosis. Satisfactory replies were obtained from 100, or 40 per cent, of the series. Of the 100 cases in which a diagnosis of neurosis had been made without important accompanying physical diagnosis, definite improvement or symptomatic cure in forty had followed hospital or dispensary care. In thirty-four the condition had remained in statu quo, two were definitely symptomatically worse, and in twenty-four definite evidence of organic disease had become manifest since discharge. Of the latter group the time interval between the patient's previous discharge from the hospital and the discovery of the organic pathologic changes was never more than two years and averaged eight months. In seven of these cases death occurred and was attributed to (1) abdominal carcinomatosis, (2) carcinoma of the liver, (3) gastric carcinoma, (4) disease of the coronary arteries, (5) Addison's disease, (6) pellagra and (7) myocardial degeneration. Of the remaining seventeen cases in which evidence of organic disease had developed, the diagnoses were (1) diabetes mellitus, (2) gallbladder disease (three cases, all proved by operation), (3) duodenal ulcer, (4) pulmonary tuberculosis (two cases), (5) ureteral stone, (6) chronic appendicitis, (7) Buerger's disease, (8) suppurative mesenteric adenitis, (9) cardiovascular renal disease with hypertension, (10) renal calculus, (11) uterine myoma, (12) pregnancy, (13) mitral stenosis and (14) toxic goiter. All these diagnoses were confirmed by laboratory, roentgen or operative results. Analysis of the previous records in these cases disclosed symptoms which in most instances might or should have led to the proper diagnosis at the time of the original examination. The author points out that this is an exceptionally high percentage of mistaken diagnoses and that the diagnosis of neurosis by exclusion is fraught with considerable danger. It is important, therefore, to recognize the definite characteristics of neurosis, the most important of which are the anxiety state, neurasthenia, compulsion neurosis and hysteria. Neurosis is in reality an emotional instability out of proportion to actual organic impairment. The point is frequently overlooked however, that neurosis and organic pathologic changes often coexist and either may be the forerunner of the other or they may be entirely separate from each other. The points brought out by this simple presentation of follow-up information deserve the careful consideration of every practicing physician.

Medical Economics

THE ST LOUIS MEDICAL SOCIETY PLAN

MAJOR G SEELIG M D
St Louis

The St. Louis Medical Society toward the end of 1933 created, by resolution, the Code and Contract Board (the name of which was later changed to the Medical Economics Board), made up of three members. This board established as its objective a survey of all the factors entering into the economic fabric of medical practice and arranged a close cooperative alliance with such other correlated committees of the St. Louis Medical Society as the Medicolegal, Censors, Ethics and Hospital committees. It furthermore appointed subcommittees for the study of special topics. To one of these subcommittees was delegated the task of collecting, studying and evaluating the various schemes and plans that were rapidly developing throughout the country and that were being tried out as ameliorative economic measures. The Medical Economics Board also maintained a close contact with the Missouri State Medical Association and the American Medical Association, and both of these agencies have been helpful throughout the period of organization.

As a result of the activities of the Medical Economics Board of the St. Louis Medical Society, the Medical Economic Security Administration was established comprising three bureaus: the Medical-Dental Service Bureau, Group Hospital Service and Central Admitting Bureau. Up to date the first two of these bureaus have been established and are functioning satisfactorily. The board of directors of the Medical-Dental Bureau is made up exclusively of members of the St. Louis Medical Society, the St. Louis County Medical Society, the Mound City Forum (Negro Medical Society) and the St. Louis Dental Society. Through its agency, patients are enabled to meet their doctor and their hospital bills on a basis of time budgeting. The results to date indicate an eagerness on the part of a large group of the working class to avail themselves of this opportunity. All financial arrangements are completed only after they have met with the assent of the individual doctor, dentist or hospital concerned in the problem of the patient seeking help.

The Board of Group Hospital Service is made up of representatives of the public, the hospitals that are in the group: the St. Louis Medical Society and the St. Louis County Medical Society. In essence, the activity of Group Hospital Service consists in providing for employees in groups of ten, three weeks free hospital service (exclusive of physicians, roentgenologists, pathologists' and special anesthetists' fees) on the payment of \$9 a year, plus \$1 registration fee by each individual who enrolls. The response to this activity has thus far been most encouraging and we feel that we in St. Louis are on the road to provide sane, satisfactory and highly desirable hospital care for that great body of the public which is in a state of economic fixation.

Our whole scheme is based on the so-called Washington Plan. We have, however, introduced such modifications as have been demonstrated to be desirable as a result of the experience of the Washington group. For example, Group Hospital Service in St. Louis will not enroll, as members, any group that is working under any prepayment plan or other scheme that denies free choice, by the group members of physician or hospital. The hospitals constituting Group Hospital Service must agree not to extend any preferential contracts to industrial organizations, and employees are enrolled by Group Hospital Service only on the provision that their dues are to be paid

by their employers through a system of payroll deduction at the source. An exception is made in the instance of government employees, on account of the legal prohibition against payroll deductions by government agencies.

The plans outlined are much too complex to permit detailed description within short compass. The important points that merit consideration and that we in St. Louis believe deserve commendation are the following. The public, the hospitals, industry and commerce have accepted the lead of the St. Louis Medical Society, in an attempt to break down the impasse created by economic factors that were rapidly doing great damage to the public health, happiness and comfort. The St. Louis Medical Society has succeeded in no small degree in convincing the thinking public that organized medicine is concerned chiefly and primarily with public health and only secondarily with those material benefits which flow indirectly to the physicians themselves and without which the individual practitioners cannot possibly carry on. The organized profession of St. Louis has never assumed an attitude of dominating autocracy, but on the contrary, has been able to work smoothly and cooperatively with every other health agency in the city and with every group of intelligent laymen whose chief interests lie beyond the field of public health, the organized profession however, has modestly but none the less specifically tried to make it plain that health and disease come within their bailiwick as experts, just as bridge and levee construction comes within the realm of the engineers, and that any scheme or plan that aims at health security and that ignores the counsels of medical experts must of necessity rest on a dangerously insecure foundation.

4952 Park View Place

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal—Dr. Walter A. Minsch, Athens, has resigned as health officer of Limestone County on account of illness. Dr. William J. B. Owings, Vernon, has been appointed health officer of Escambia County, succeeding Dr. Edward F. Goldsmith, Jr., Brewton, who resigned to engage in private practice in Pritchard.

Outbreak of Poliomyelitis—With five new cases of poliomyelitis, the total number of cases in Alabama was 199 with twelve deaths. The *Chicago Tribune* reported July 26. The outbreak had by the middle of July involved about ten counties in the northwestern corner of the state and had spread to three adjoining counties in Tennessee and Mississippi to a slight degree. According to the U. S. Public Health Service, the outbreak appears to be comparable to that which occurred in north central North Carolina last year in intensity, mildness of the individual cases, high proportion of rural cases and low age distribution. It is presumably a favorable indication that the Alabama outbreak became apparent some four weeks later in the season than did the outbreak in North Carolina.

ARKANSAS

Report of Impostor Who Collects Instruments—Dr. Jones H. Lamb, Paragould, reports that a man posing as manager and owner of Copley and Company, reputedly an instrument supply concern in Nashville, Tenn., has been calling on physicians to collect instruments for adjustment and polishing. A letter from a Nashville supply house, answering an inquiry from Dr. Lamb when he did not receive his instruments state that the firm of Copley and Company is not known in that city.

Dedication of Medical School Building—Dr Thomas M Pinson, Kerrville, Texas, the first and only graduate of the school fifty-six years ago was guest of honor at the recent dedication of the new building of the University of Arkansas School of Medicine, Little Rock. Other speakers included Gov J Marion Futrell, Mrs J W Velvin, president of the Arkansas Federation of Women's Clubs, John C Futrell LL.D. president, University of Arkansas, Lieut Gov Lee Cazort and Mr Marion Wasson, a member of the board of trustees. Dr Frank Vinsonhaler, dean of the medical school, presided. The building, which is five stories high with a sixth floor in the center, was constructed at a cost of \$500,000. Its exterior is of buff-colored face brick trimmed with Arkansas limestone. The Isaac Folsom Clinic occupies the first floor and part of the second, which is the main floor. On the main floor are located the offices of administration, library and cafeteria. The pathology and bacteriology departments occupy the third floor, containing laboratories and offices for each, a necropsy room, a museum of pathology and an amphitheater. The fourth floor houses the departments of physiologic chemistry and physiology

New medical school building

and pharmacology, with laboratories and offices for each. The departments of anatomy and histology with laboratories, offices and a lecture room, are located on the fifth floor. The sixth floor provides space for research laboratories and cages for dogs and other animals; the department of operative surgery is also located on this floor.

COLORADO

Radiologic Conference—The midsummer radiologic conference sponsored by the Denver Radiological Club will be held at the Hotel Shirley-Savoy, Denver, August 5-7. Guest speakers on the program will include:

Dr Eugene P. Pendergrass, Philadelphia, Chaoul Therapy as Practiced in European Clinics.
Dr John D. Camp, Rochester, Minn., Roentgenologic Findings in Patients with Sciatica and Low Back Pain.
Dr James M. Martin, Dallas, Texas, Radiation Therapy in the Treatment of Carcinoma of the Intra Oral Cavity, Larynx and Pharynx.
Dr Clyde K. Emery, Los Angeles, Management of Carcinomas of the Breast.

Visiting speakers of the Radiological Club of Omaha include Drs Howard B. Hunt, Anders P. Overgaard, Albert F. Tyler, Tenney, Tennyson, Harris, James F. Kelly and Edward W. Rowe, Lincoln. Wednesday evening there will be a joint meeting with the Medical Society of the City and County of Denver with Dr Theodore E. Beyer, president of the society, presiding. Speakers will be Dr Camp and Dr Martin on "Osteoporosis and Its Importance in Medical Diagnosis" and "The Physician's Responsibility to the Cancer Patient" respectively. Thursday morning will be devoted to a symposium on gastrointestinal disease and Thursday afternoon to a round table discussion followed by a symposium on diagnostic radiology. A round table discussion Friday afternoon will deal with therapeutic radiology.

CONNECTICUT

Personal—Dr Marvin A. Stevens, formerly football coach at Yale University and since 1932 on the coaching staff of New York University, has been appointed assistant clinical professor of orthopedic surgery, Yale University School of Medicine, New Haven. He has also been made orthopedist in the Yale University Department of Health and to the staff of New Haven Hospital.

Relic from Charter Oak Presented to Hartford—The city of Hartford was presented by Dr Charles Coffing Beach with a three foot piece of wood from the original Charter Oak. June 16 the three hundredth anniversary of Thomas Hooker's

arrival in Hartford. According to the *New England Journal of Medicine*, this relic includes part of a knot hole in which is believed to have been hidden the original charter in 1636. The tree was blown down in a storm in August 1856 and this relic has been passed on through the Buckleys, Stuarts and Beaches. The piece presented to the city stands encased in a glass cabinet, on the back of which is embossed a brief history of the tree.

GEORGIA

Society News—Dr Shelley C. Davis, Atlanta, read a paper on "The Chronically Diseased Cervix as a Focal Point of Infection" before the Fulton County Medical Society in Atlanta July 16. The society was addressed, July 2, by Drs Thomas E. McGeachy, Decatur, and J. Edgar Paulin, Atlanta; their paper was entitled "Dissecting Aneurysm of the Aorta."—At a meeting of the Thomas County Medical Society in Meigs, June 17, Drs Ernest F. Wahl, Thomasville, read a paper on "Effect of Nervous Influences on Digestion" and William W. Jarrell, "Treatment of Rural Syphilis." Dr James R. Dykes, Thomasville, discussed "A Proposed Venereal Disease Clinic for Thomas County."—The Sixth District Medical Society was addressed at Dublin, June 24, among others by Drs Bernard L. Helton, Sandersville, on "Diathermy in General Practice," and Robert G. Ferrell Jr., Dublin, "Acute Osteomyelitis."—The Burke-Jenkins-Screven Counties Medical Society was addressed at Millen, June 11, by Drs Quimby A. Mulkey, Millen, on "Diagnosis and Treatment of Head Injuries," and Herbert C. Schenck, Atlanta, "Present Status of Tuberculosis in Georgia with Suggestion for Improvement."—The Carroll County Medical Society sponsored a public lecture at the Carroll Theater, Carrollton, June 23; Dr Hal M. Davison, Atlanta, spoke on "Malaria Control."

ILLINOIS

Personal—Dr Lawrence F. Isenhardt has been named health officer of Mount Carroll, succeeding Dr Samuel P. Colehour.—Dr Kenneth G. Bulley of the staff of the Wisconsin State Sanatorium, Statesan, Wis., has been named superintendent of Kane County Springbrook Sanatorium, Aurora.

Study of Traffic Accidents—The University of Illinois this autumn will inaugurate a study of the causes of traffic accidents and the efficacy of methods to reduce the motor toll, the *Chicago Tribune* reports. Students will be required to pass a driver's license examination to obtain a school permit to use an automobile and the cars will have to pass a mechanical test. A detailed record will be kept of all available pertinent information on the 500 automobiles for which student permits are issued. It is hoped to gain information of value to street safety engineers.

Society News—The Sangamon County Medical Society held its annual picnic at the Wentworth Club and golf tournament at the Oakcrest Country Club, July 23.—The McHenry County Medical Society was addressed, July 16, by Dr Clifford G. Grulee, Evanston, on "Care of Premature Infants."—Dr George J. Musgrave, Chicago, discussed "Nasal Accessory Sinuses" before the Christian County Medical Society, July 23.—Dr M. Herbert Barker, Chicago, addressed the Whiteside County Medical Society, June 25, on "Treatment of Hypertension with Special Reference to the Cyanates."—At a meeting of the McLean County Medical Society in Bloomington, June 9, Dr Archibald L. Hoyne, Chicago, discussed "Treatment of Meningococcic Meningitis."—Dr Paul A. O'Leary, Rochester, Minn., discussed "Modern Treatment of Syphilis" before the Peoria City Medical Society, June 23.

CHICAGO

Annual Golf Tournament—The Chicago Medical Society will hold its annual golf tournament at Olympia Fields August 12. While many prizes will be awarded to members of the society and their guests, competition for the Van Derslice Cup is open only to past presidents, trustees, councilors alternate councilors and branch officers. The fee of \$4 includes the charge for dinner in the evening. All members of the society are urged to play in the tournament and bring their guests.

Campaign Against Rabies—A movement was launched to place antirabic serum on the list of free medicines furnished by Cook County. The *Chicago Tribune* reported July 25 as a step in the campaign now being waged against the disease by officials in Chicago and the county. A special campaign will be carried on against unmuzzled dogs with the adoption of an emergency ordinance permitting the destruction of any dog claimed within twenty-four hours and a quarantine has been

imposed forbidding the transportation of dogs into or out of Cook County. The *Tribune* reported, July 27, that 242 cases of dog bites had been reported within the previous two and one-half days.

KANSAS

Second Graduate Course—The Kansas State Board of Health opened its second graduate course in obstetrics and pediatrics in Salina, July 27, to continue for four weeks at weekly intervals. Other places where the course will be given are Ellsworth, Hays, Osborne and Concordia. Lectures in the course, which is financed by social security funds, will be given by Drs Leroy A. Calkins, professor of obstetrics and gynecology, University of Kansas School of Medicine and Lucius E. Eckles, Topeka.

Committee on Tuberculosis—The appointment of a committee on control of tuberculosis by the Kansas Medical Society was the outgrowth of a conference in Topeka May 26, attended by representatives of the state board of health, the Kansas Tuberculosis and Health Association, the Kansas Tuberculosis Sanatorium and the state medical society. The conference was called to consider means whereby these agencies could best coordinate their efforts in this field. The purpose of the committee will be to serve in an advisory capacity to the various groups engaged in tuberculosis work. Dr Howard L. Snyder, Winfield, president of the Kansas Medical Society, was named chairman ex officio, and Dr Charles F. Taylor, Norton, vice chairman. Other members appointed to date according to the state medical journal, are Drs Charles H. Lerrigo, Earle G. Brown and Forrest L. Loveland, all of Topeka; Harry L. Chambers, Lawrence, and Harold H. Jones, Winfield. The first meeting of the committee was to be held in June to discuss and organize activities for the coming year.

MAINE

Society News—At a meeting of the Aroostook County Medical Society in Houlton, June 11, Drs William V. Cox, Lewiston, discussed 'Diagnosis and Treatment of Brain Tumor' and Magnus F. Ridlon, Bangor, 'Carcinoma of the Uterus'.—Dr Julius C. Oram, Portland, addressed a recent meeting of the Portland Medical Club in Portland on gastro-intestinal manifestations of allergic conditions.

MARYLAND

Rocky Mountain Spotted Fever—Eight cases of Rocky Mountain spotted fever and three deaths have been reported in Maryland, up to July 1, according to *Baltimore Health News*. Since Jan. 1, 1930, 245 cases have been recorded in the state, twenty one of which have been fatal.

Typhoid Carriers—The names of sixteen typhoid carriers were added from January 1 to May 31 to the register kept by the state department of health. Ten of these were found in 1935 and six during the first five months of this year. Seventy-nine cases of the disease were traced to these sixteen carriers, sixty-seven to those discovered in 1935 and twelve to those found since the beginning of the current year. The register of typhoid carriers, begun in 1929, contains 153 names. Fifty-two of these were males and 101 females, to whom 642 cases of typhoid have been traced. The majority of cases occurred between 1911 and 1935 but the total includes fifteen cases in Cecil County in 1884 that were traced to a milk handler. The number of known active carriers in the counties on June 1 was 128, forty-one males and eighty-seven females. The number of cases traced to them is 551. A separate register of carriers discovered in Baltimore is kept by the city health department, the number of active carriers is twenty-one. According to the state department of health seventy-one carriers are housewives, eleven include cooks, domestics, a waiter, a market attendant, eighteen milk handlers, eight sea food handlers, three cannery workers, no occupation was listed for twenty-eight carriers. One of the carriers is 87 years of age and is believed to have been responsible for about fifty cases between 1916 and 1935.

MASSACHUSETTS

Anniversary of Student Medical Society—A dinner was recently held at the Harvard Club, Boston, to observe the one hundred and twenty-fifth anniversary of the Boylston Medical Society, which is probably the oldest students' medical school organization in this country. A new catalogue of the society was issued to commemorate the occasion. Speakers included Drs Henry Jackson Sr., George R. Minot and C. Sidney Burwell, dean of the Harvard Medical School and president-elect of the society. Dr John Lovett Morse, faculty president of the society in 1910 and toastmaster at the centennial cele-

bration, and Dr David Cheever, son of the late Dr David W. Cheever, who spoke at the centennial celebration, also gave addresses. Dr Jackson Jr., awarded the Boylston Prize for the year 1936-1937 to Mr. Barnard P. Todd for his dissertation on the etiology of rheumatic fever. The society was founded by Ward Nicholas Boylston, who also established the Boylston Medical Library. Mr. Boylston was a merchant in Boston.

MICHIGAN

State Society Night—The Calhoun County Medical Society was host to officers and committee members of the Michigan State Medical Society at a dinner meeting in Battle Creek, June 2. Speakers included:

Dr Grover C. Penberthy, Detroit, president of the state society. Five Year Program of the Michigan State Medical Society.
Dr Henry Look, Flint, chairman of the council. Advantages of Unity.
Dr Clifford T. Ekelund, Pontiac, secretary. Who Wants Socialized Medicine?
Dr James H. Dempster, Detroit, editor of the state journal. How Not to Write the Case History.

Dr Rollin C. Winslow, president of the Calhoun County Medical Society, presided at the meeting.

Medical Clubs Desire Charter—At a meeting of the medical clubs of Allegan and Van Buren counties in Allegan, June 17, the former voted to seek a charter to organize as the Allegan County Medical Society. The meeting followed golf and dinner at the Ot-Well-Egan Country Club. The afflicted-crippled child problem and the filter system were discussed, the speakers included Drs Louis Fernald, Foster Bay City, chairman, public relations committee of the state society, as guest, Enid T. Andrews, Kalamazoo; Roy H. Holmes, Muskegon; Aaron V. Wenger, Grand Rapids; and Mr. William J. Burns, Lansing, executive secretary of the state medical society.

NEW JERSEY

Personal—New Jersey delegates to the American Medical Association and Mr. Albert Skean, director of the Atlantic City Convention Bureau, were guests of honor at a dinner given in Atlantic City in appreciation of their efforts to bring the 1937 session of the Association to Atlantic City. The physicians were Drs. Walt P. Conaway and Hilton S. Read, Atlantic City; John F. Hagerty, Newark, and Ephraim R. Mulford, Burlington.

State Society President Resigns—Dr. Francis R. Hausling, Newark, who was installed as president of the Medical Society of New Jersey at the recent annual meeting, has resigned because of ill health and Dr. Spencer T. Snedecor, Hackensack, president-elect, has been declared president by the board of trustees. Dr. William G. Herrman, Asbury, as first vice president, has become president-elect. Dr. William J. Carrington, Atlantic City, first vice president. Dr. Edward M. Zeh, Hawkes, Newark, was made second vice president.

NEW YORK

Dr. Gregory Retires—Dr. Willis G. Gregory, dean of the University of Buffalo School of Pharmacy since 1890 and professor of pharmacy since 1886, retired this year, aged 79. Dr. Gregory graduated from the University of Buffalo School of Medicine in 1882 and took a degree in pharmacy in 1886. He was a member of the state board of pharmacy for thirty years and of the U. S. Pharmacopoeial Revision Committee from 1890 to 1920 and has been president of the New York State Pharmaceutical Association. He retains his teaching position at the university.

Physicians' Home Seeks Endowment—The corporation known as The Physicians' Home, which recently reorganized, plans a vigorous campaign to finance a permanent home for aged and infirm physicians. Dr. Charles Gordon Heyd is president and Drs. Warren Coleman and Silas F. Hallock are vice presidents of the corporation. Dr. Benjamin Wallace Hamilton is secretary and Dr. Joseph J. Eller, treasurer. All are of New York. The board of directors was enlarged from fourteen to thirty-three members from all parts of the state. The Physicians' Home, which was incorporated June 4, 1919, has found it possible to maintain only from four to seven guests. There has been a large waiting list. The present endowment is about \$130,000.

Society News—The Endicott Johnson Medical Department entertained the Broome County Medical Society, the Binghamton Academy of Medicine and the Binghamton Psychiatric Society, June 29, at the Binghamton Country Club. Major Gen. Charles R. Reynolds, surgeon general, U. S. Army, spoke on 'The Responsibility of the General Practitioner in the Scheme of National Defense.'—Dr. George H. Whipple,

Rochester, among others, addressed the Cavuga County Medical Society, June 18, on anemia—Dr Walter S. Thomas Clifton Springs addressed the Cortland County Medical Society, June 19, on Differential Diagnosis of the Adenopathies.—The Rockland County medical and bar associations held their annual joint meeting June 17 at the Rockland Country Club

OHIO

Occupational Disease Program—With an appropriation of funds under the Social Security Act, the Ohio State Department of Health has launched a program for control of occupational disease under the direction of the division of industrial hygiene. For the fiscal year begun July 1 \$28,000 was made available from federal funds, which with the departmental appropriation of \$5,200 made possible the addition to the staff of five technically trained persons and a secretary, with traveling expenses and an allowance for laboratory equipment and supplies. Dr. William Eugene Masters, Columbus, has been appointed medical supervisor and Dr. Kenneth D. Smith, recently health commissioner of the city of Marion, assistant medical supervisor. Other appointments are those of Mr. C. B. Young, Columbus, as chemical engineer, Mr. Clayton Smucker, Columbus, as chemist, and Mr. A. R. Morrison, also a chemical engineer as technical assistant. All these men have recently had a month of intensive training under the technical staff of the U. S. Public Health Service. The program is divided into immediate and long range projects, the first covering investigation of the more urgent or profound cases or complaints of occupational disease, the second, physical examinations of workers subjected to important hazards and various types of surveys. The first project of the latter category will be a study of silicosis, for which a newly equipped laboratory has been set up in Columbus and a traveling automobile laboratory for field examinations provided. Dr. Emery R. Hayhurst, chief of the division of industrial hygiene and consultant in occupational diseases, is in charge of the expanded program.

OREGON

Personal—Dr. Neil F. Black of the U. S. Public Health Service, stationed at San Francisco, has been appointed health officer of Klamath County.—Dr. Rachel C. Sparks, physician to Oregon State College, Corvallis, for eight years, has severed her connections to devote her time to private practice.

Society News—At a meeting of the Jackson County Medical Society in Medford June 5, Dr. Richard B. Dillehunt, Portland, gave an address on abnormal conditions in children's feet. Dr. Henry H. Dixon, Portland, discussed psychiatric problems.—Dr. Morris Fishbein, Chicago, editor of *THE JOURNAL*, addressed the Multnomah County Medical Society, Portland, July 1, on "Organized Medicine and New Forms of Medical Practice."

TENNESSEE

Flexner Lectures at Vanderbilt—Dr. Thorvald Madsen, director of the State Serum Institute of Denmark, Copenhagen, will deliver the fifth series of Abraham Flexner Lectures at Vanderbilt University School of Medicine during the 1936-1937 session. Dr. Madsen was educated in Copenhagen and has been director of the serum institute since 1902. He has been chairman of the Health Section of the League of Nations since 1921.

Joint Medical Meeting—The medical societies of Alcorn and Tishomingo counties in Mississippi, the Five County Medical Society (Hardin, Lawrence, Lewis, Perry and Wayne counties) and the Tri-County Medical Society (Chester, Decatur and Weakley counties) held a joint meeting at Shiloh National Park June 30. Speakers were Drs. LeRoy B. Brackstone, Iuka, Miss., on "Acute Hemorrhagic Nephritis in Children," John H. Tilley, Lawrenceburg, "Intestinal Obstruction," John C. Pearce, Jackson, "Prenatal Care and Some Pathologic Conditions in Obstetrics," William O. Baird, Henderson, "Sudden Deaths," and Claud F. Gilbert, Corinth, Miss., "Skull Fractures with Brain Injuries."—Dr. Robert S. Leach, Knoxville, addressed the Knox County Medical Society, June 23, on "Ocular Vertigo."—Drs. John G. Moss and Wallace L. Poole, Johnson City, addressed the Washington County Medical Society, July 2, on pelvic pain and poliomyelitis.

UTAH

Society News—Speakers at a meeting of the Central Utah Medical Association in May in Salina were Drs. William R. Tyndale, Salt Lake City, president of the Utah State Medical Association, on amebiasis; John R. Anderson, Springville, on arachnidism; George A. Curtis, Salt Lake City, secretary of

the state society, socialized medicine, and Mr. William H. Tibbals, executive secretary, medical economics.—The Salt Lake County Medical Society held a golf tournament with the legal profession at the Fort Douglas golf course, June 2. At a clinical meeting in May case reports were presented by Drs. David C. Budge, Logan, on chronic infection of the leg; David E. Smith, painless jaundice; Oza J. LaBarge, cystic disease of bone, and Alfred C. Callister, mechanical asphyxia caused by cleft palate combined with retraction of the lower jaw.—At a recent meeting of the Weber County Medical Society, Ogden, Drs. Howard K. Belnap and Charles Elmer Barrett spoke on respiratory and alimentary allergy, respectively.

WASHINGTON

Personal—Dr. John A. Kahl, Portland, has been appointed health officer of Clark County with headquarters at Vancouver.—Dr. Frances Houston, physician to women at the University of Washington, Seattle, has discontinued this work and will engage in private practice.

Lumberman's Clinic Practice Declared Illegal—The Supreme Court of Washington has recently affirmed a ruling of a lower court that the Lumberman's Clinic, Olympia, was illegally engaged in practicing medicine. The action was based on the claim that the clinic is not a hospital association under the law and therefore illegally entered into contracts with employers to give medical attention to their employees. Both Thurston County as plaintiff and the clinic as defendant appealed the case. It was held that the judgment should include a provision that if reorganization was not effected within ninety days the court would enter a judgment of ouster.

Memorial to Pioneer Physician—A bronze bust on Dr. David Swinson Maynard, one of the original settlers and the first physician of Seattle, has been made for the King County Medical Society under the public works of art project. The Puget Sound Surgical Society provided a pedestal. Dr. Maynard was a native of Vermont and after practicing twenty years near Cleveland joined an emigrant train to the Northwest in 1850. He lived in various places for two years but in 1852 joined the original company in making a permanent settlement on the site named Seattle. Until his death in 1896 he took an active part in the civic, social and medical affairs of the city, according to *Northwest Medicine*.

WISCONSIN

The "Spectro-Chrome" and "Hocus Pocus"—A unanimous verdict that "the application of light rays by the use of the Spectro-Chrome instrument has no substantial healing or curative effect on diseases of the human body" was rendered by a jury in a libel suit of E. A. Ernest, Milwaukee, against the Milwaukee Journal. The newspaper in an article published Nov. 19, 1933, had called the Spectro-Chrome a "hocus pocus" healing device. Mr. Ernest was at that time a distributor for the apparatus, which is made by the Spectro-Chrome Institute, Malaga, N. J., controlled by one Dinshah P. Ghadiali. According to the *Milwaukee Medical Times*, Ghadiali threatened to sue the newspaper unless a retraction was made. He did not sue nor was a retraction published. Ernest sued however for \$150,000 damages and \$35,000 special damages. The newspaper defended itself squarely on the statement that Spectro-Chrome was "hocus-pocus" and had no curative value other than mental. Its contention was that exposure of such a mischievous and dangerous quackery and fraud was a public duty and that the newspaper article was fair comment. Spectro-Chrome was the subject of an article in *THE JOURNAL*, Jan. 26, 1924, which was the basis for most of the newspaper article.

District Meetings—The Fifth Councilor District Medical Society held a meeting June 25 at Big Cedar Lake. Speakers were Drs. Andrew B. Rivers and James T. Priestley Jr., Rochester, Minn., on "Treatment of Peptic Ulcer and Acute Appendicitis," respectively; Edward L. Cornell and Ralph B. Bettman, Chicago, "Treatment of Toxemias of Pregnancy," and "Treatment of Injuries of the Chest," respectively. In the evening Dr. Carl W. Eberbach, Milwaukee, spoke on "Medical Practice in Labrador" and Dr. Ralph M. Carter, Green Bay, president of the state society, on organized medicine.—At the annual meeting of the Seventh Councilor District at Tomah June 10 speakers included Drs. Edwin J. Kepler, Rochester, Minn., on "Recent Advances in Endocrinology," William S. Middleton, Madison, "Diagnosis and Treatment of Heart Disease," Harry R. Foerster, Milwaukee, "Common Skin Diseases," and Mr. J. George Crownhart, Madison, secretary of the State Medical Society of Wisconsin.

'The Immediate Future'—Dr William F Braasch, Rochester, Minn., was the dinner speaker at the annual meeting of the Sixth Council District in Fond du Lac, June 30, on 'The Future of Medicine Under State Control'. Guest speakers at the scientific session included Drs Harry E Mock and Clarence F G Brown Chicago, on 'Diagnosis and Management of Obscure Abdominal Lesions' and 'Medical Management of Gallbladder Disease' respectively. Speakers at the annual meeting of the Fourth Council District in Lancaster in May included Drs Ralph M Carter, Green Bay, president of the state society, on 'State Medicine and the Private Practitioner' and Eben J Carey Milwaukee 'Medical Science and the Public'.

ALASKA

Typhoid Quarantine—Settlements in the Bristol Bay region were under quarantine, July 26, with all persons prohibited from leaving until the danger of spreading an outbreak of typhoid had passed. Dr Walter W Council, territorial health officer, wired other Alaskan cities that no fishermen from the affected salmon cannery hamlets could board airplanes or boats. With the fishing season ended, the quarantine prevented the annual hurried migration of fishermen from the cannery settlements to celebrations in Alaskan towns or farther south to Seattle, Portland and San Francisco for the winter.

GENERAL

Aero Medical Association—The eighth annual meeting of the Aero Medical Association will be held at Los Angeles August 28-30, with headquarters at the Biltmore. Speakers will include the following:

- Dr Bascom L Wilson major medical corps U S Army An Analysis of the Causes of Rejection of 500 Applicants for Flying Training
- Dr Isaac H Jones Los Angeles Résumé of Problems in Aviation Medicine
- Dr John R Poppen lieutenant commander medical corps U S Navy Equilibrium Functions in Instrument Flying
- Dr David C Gæde lieutenant (j. g.) U S Navy Neuro-orenlatory Asthenia—Its Nature and Prevalence in Flying Personnel
- Dr Charles H Gowan Glendale, Calif Carbon Monoxide Poisoning
- Dr Harry V Wurdemann Seattle Statistics of Physical Examination for Flying with Special Reference to Continuation of Training by Students
- Dr Herbert F Fenwick, Chicago Fatigue—Its Relation to Ocular Muscle Balance and the Schneider Index
- Dr Wade Hampton Miller Kansas City Mo Fatigue—Some Special Effects and Tests

Women to Organize for Cancer Control—With the appointment of officers and committees, a definite step was recently taken in the plan to organize a 'Women's Field Army' in the program for control of cancer. The movement began in 1934, when the General Federation of Women's Clubs became interested in the campaign carried on by the American Society for the Control of Cancer, but it did not take shape until this year. Grace Morrison Poole, from 1932 to 1935 president of the General Federation of Women's Clubs, has been named chief adviser to the Women's Field Army, and Marjorie B Illig has been designated lay field representative of the American Society for the Control of Cancer. Both have their headquarters at the central office of the society, 1250 Sixth Avenue, New York. The Women's Field Army will serve as the official lay organization in the national campaign. Each state will have a commander and "vice commanders" in proportion to the population of the state, captains will be appointed to act as leaders in the local work. Advisory committees will be named, composed largely of medical men but with adequate lay representation. To obtain funds for the educational activities of the army, the American society has decided to set aside a week for a national enlistment campaign, the fee to be \$1. Voluntary contributions of the federation club members have formed a fund which is now available to the state federations for cancer education projects approved by the General Federation Advisory Board on Public Health.

Hot Weather Raises Mortality Rate—With a rate of 46.4, Peoria, Ill., showed the highest mortality among eighty-six cities with a total population of 37 million, for the week ended July 18 according to the U S Department of Commerce. A mortality rate of 6 was reported for Peoria for the corresponding period last year. The highest infant mortality rate (245) also appears for Peoria. The mortality rate for the eighty-six cities was 17 against a rate of 10.4 for the corresponding period last year. The sharp increase in mortality for this week resulted from the extreme heat wave in midwestern states. There were 12,183 deaths during the week, as compared with 7,439 in the corresponding week of 1935 representing an increase of 4,744 deaths or 64 per cent. From the standpoint of mortality the heat wave of 1936 is much more severe than the heat wave of 1934 the department points out.

Minneapolis reported a mortality rate of 40.3 as compared with 8.4 in 1935, Evansville, Ind., 36 in 1936 against 14.1 in 1935. Indianapolis, 33.5 in 1936 as compared with 14.1 in 1935, and Dayton, Ohio, showed a recent rate of 33.6 against a rate of 9.4 in 1935. The annual rate for eighty-six cities for the twenty-nine weeks of 1936 was 13 as against a rate of 12 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Pan-Pacific Surgical Congress—The second congress of the Pan-Pacific Surgical Association will be held in Honolulu, T H, August 6-14, with headquarters at the Royal Hawaiian Hotel. Officers are Drs George W Swift, Seattle, president, Nils P Larsen, Honolulu, vice president, and Forrest J Pinkerton, Honolulu, secretary. Among speakers listed on the tentative program were:

- Dr John M Wheeler New York A New Operation for Spastic Entropion of the Lower Eyelid
- Dr Harvey B Stone Baltimore Gallbladder Disease from the Surgical Standpoint
- Dr Arthur M Shipley Baltimore The Diaphragm as a Surgical Problem
- Dr Fred W Rankin Lexington Ky Evolution of Surgery of the Large Bowel and Rectum
- Dr Ralph C Matson Portland Newer Achievements in Thoracic Surgery
- Dr Carl J Johannesson Walla Walla Wash Difficulties of Roentgenologic Study of Postoperative Stomach and Small Intestine
- Dr Paul B Magnuson Chicago Grafting Experiences with Fresh and Ununited Fractures of the Neck of the Femur
- Dr Hugh H Tront Roanoke Va Carcinoma of the Breast
- Dr J Hua Lin Peiping China Foreign Bodies in the Air and Food Passages
- Dr J Nishiwaka Sapporo Japan Observations on Surgery of the Pancreas
- Dr J Hardie Neil Auckland N Z Bronchoscopy Anatomy

Two community health meetings will be held Monday and Thursday evenings, August 10 and 13. Among speakers will be:

- Dr Henry W Cave New York Appendicitis—Its Cause and Treatment
- Dr Frederic A Besley Waukegan Ill The Tragedy of Accidents
- Dr Hulett J Wyckoff Seattle, Arthritis
- Dr Malcolm T MacEachern Chicago Cancer—Its Course and Curability
- Dr Howard L Updegraff Los Angeles Growing Old Gracefully

Dr MacEachern will conduct a hospital institute at Queen's Hospital, August 11-12, under the auspices of the association. The Pan-Pacific Surgical Association was formed during the first congress, held in Honolulu, Aug 14-24, 1929, which was arranged by the Pan-Pacific Union.

Nasal Spray as Preventive of Poliomyelitis—Recent experimental work by Drs Charles Armstrong and Walter T Harrison of the National Institute of Health, Washington, D C., in preventing poliomyelitis in monkeys by the use of a nasal spray has excited so much interest and speculation that the U S Public Health Service deems it desirable to issue the following statement:

'The evidence regarding this method is as yet based entirely on animal experimentation and the proposed spray is not at present to be regarded as of proved value in the prevention of poliomyelitis in man. Perhaps it would be advisable to await the results of further trials before giving the method general application. If it is desired to use the solution it should be sprayed into the nostrils three or four times on alternate days, and thereafter weekly during the presence of poliomyelitis. The spray tip should be pointed upward and backward at an angle of about 45 degrees, and the spraying should be thorough enough to reach the pharynx as well, when a bitter taste will be noted. The early applications at least should be administered by a physician. The experimental work on animals is still being pursued. Therefore, the tentative procedure is subject to such changes as may be dictated by future findings. The most effective solution so far developed during experimentation on monkeys is prepared as follows:

Solution A Dissolve one gram (1 Gm.) of picric acid in 100 cc of physiologic salt solution (0.85 per cent). (Warming facilitates solution of the picric acid.)

Solution B Dissolve 1 gram (1 Gm.) of sodium aluminum sulfate (sodium alum) in 100 cc of physiologic salt solution (0.85 per cent). Any turbidity in this solution should be removed by filtering one or more times through the same filter paper.

Mix solutions A and B in equal amounts. The resulting mixture which contains 0.5 per cent picric acid and 0.5 per cent alum is sufficiently antiseptic to prevent the growth of organisms and is ready for use as a spray. Home-made concoctions are not favored.

While predictions cannot be made concerning epidemics, it is the opinion of the public health service that there are no indications that poliomyelitis will be unduly prevalent this summer."

Debate on the Induction of Premature Labor in Primigravidas

At the Section of Obstetrics of the Royal Society of Medicine, a debate took place on the motion "That the induction of premature labor should not play any part in the treatment of pelvic contraction in primigravidas." More than twenty speakers took part and the motion was carried by 40 votes to 18. A. J. Wrigley said that few, if any, present would advise induction before the estimated thirty-sixth week. If the disproportion was obvious before that, the majority would advise cesarean section. During the last few years, thousands of unnecessary inductions had been performed. It was taught that, if in doubt, it was safer to induce. This wholesale intervention was accompanied by considerable risk. Prof. F. J. Browne had stated that, out of 173 deaths in nine maternity hospitals, eight followed directly on induction. The introduction of a bougie was often followed by brisk hemorrhage from separation of the placenta. Another danger of induction was rendering the action of the uterine muscle inadequate, so that complications set in. It resulted in a considerable increase of infant mortality and in some increase of maternal mortality.

Arnold Walker gave some figures on a series of 3,000 consecutive booked cases at the Willesden Maternity Hospital, which were representative of the general population. Among the 1,447 primigravidas the total infant loss in the cases in which labor was interfered with was eighteen. These included cesarean sections, forceps deliveries and craniotomies—there were no inductions—but excluded breech deliveries. Among these eighteen were deaths from hydrocephalus, antepartum hemorrhage and prematurity. Walker described what he and his colleagues termed "trial labor"—the opportunity for a deflexed head or a conical lower uterine segment to readjust itself, and for the increasing tension of the ligaments to pull down the uterus and its contents. When time had been given for this, the position could be reviewed afresh. The reasons for this policy were the frequency with which induced labor was complicated by inertia and the frequency with which the child was born dead or died.

Herbert Spencer spoke in favor of induction. Five years ago when the subject was discussed before the society the value of induction for minor degrees of disproportion was generally acknowledged. Only one London hospital had ceased to practice induction since Whitridge Williams, whose experience was limited to one case, had given it up. The present debate dealt only with primigravidas, though he knew of no reason for limiting induction to pluriparas in whom it might be attended with special risks. The value of induction could be estimated only by comparison with alternatives—trial labor, forceps, cesarean section. His use of forceps had been conservative since he learned forty-six years ago that all children delivered by forceps who died had meningeal or cerebral hemorrhage. In a series of 427 inductions at University College Hospital there was only one maternal death, a mortality of 2.3 per thousand, while the fetal mortality was just under 12 per cent. For the eighty-five primigravidas of the series, ten children died, 11.7 per cent. He held that induction should have a large part in the treatment of minor disproportion, cesarean section and forceps a small part and craniotomy (except for dead, damaged or hydrocephalic children) no part at all. He deplored the craniotomies of some hospitals.

James Wyatt supported Spencer by figures from St. Thomas's Hospital where of 3,800 deliveries labor was induced in 199

for disproportion, generally by bougies. In only sixteen, or 8 per cent, was there some morbidity, the standard being a rise in temperature to 100 F or over. Of twenty-three stillbirths in this series, five were macerated and one was a case of hydrocephalus.

Prof. Munro Kerr said that it was impossible at the thirty-sixth week to tell whether the head would go through or not in borderline cases. Adjustments took place during the later days of pregnancy and the early stage of labor, which altered the outlook completely as to the relative size of head and pelvis. With the patient in the dorsal position one was apt to grasp the head above the pelvis so as to tilt it either backward or forward and to produce anterior or posterior parietal obliquity. With the latter, matters were made to appear much worse than they were, with the former, better than they were. It was impossible to tell beforehand how the head was going to mold or what the strength of the uterine contractions would be. These two important uncertainties had always to be contended with, and it was only when labor had started that it could be said whether the head would go through the pelvis or not. In only about 10 per cent of the cases in which he allowed a trial labor to take place was spontaneous delivery not forthcoming, and his result was a fetal mortality of not more than 5 or 6 per cent, excluding extraneous conditions, such as malformations of the uterus and placenta praevia. The sooner induction in primigravidas was abolished, the better.

Leslie Williams drew attention to the difference between trial labor in domiciliary and hospital practice. In the latter it was an excellent thing, in the former it had no place, and even in the best nursing homes only a small one.

The Bureau of Human Heredity

The establishment of the Bureau of Human Heredity has been described previously. In a letter to the *British Medical Journal* the chairman, R. Ruggles Gates, F.R.S., calls attention to the interest of this new enterprise to physicians. Whether they have any particular interest in human genetics or not, it should be a cause of general satisfaction that Great Britain has been chosen as the seat of a clearing house for the scientific world of material dealing with human heredity. The British National Heredity Committee was formed in 1932 for the collection of data and the investigation of human pedigrees, as a branch of the International Human Heredity Committee, founded by the International Federation of Eugenic Organizations. The committee has now been enlarged as a council. It has secured accommodations at 115 Gower Street, London W.C.1, and in collaboration with the Galton Laboratory aims at setting up a clearing house of material on human genetics. The council consists of geneticists and leading physicians. It would welcome any material from institutions and individuals giving well authenticated data on the transmission of human traits. Family histories or pedigrees, twin studies and statistical studies are mainly contemplated. Reprints of published work are also most acceptable. Many authors may have collected pedigrees which they have been unable to reproduce in detail. The council hopes that these records may be included in the clearing house and not lost. Other objects contemplated are facilities for study, replies to inquiries and information service, but these cannot be initiated for some time.

Gift for Research to Royal College of Surgeons

The late Bernhard Baron was a generous donor to medical institutions. Though primarily concerned with the relief of sufferers, he realized the great value of advances in medical knowledge and supported it. His trustees have visited the Royal College of Surgeons and realized the importance of the researches being carried on there under difficult conditions. They have therefore made a gift of \$125,000 for new laboratories, which as a memorial to him are to be called the Bernhard Baron Laboratories.

Puncture of the Sternum as a Diagnostic Method

The sternal puncture method of obtaining specimens has become an almost routine procedure in many French clinics, enabling the hematologist to see in two or three microscopic fields in a few minutes blood elements which under ordinary conditions—specimens obtained from the ear or the finger—would necessitate hours of search. The technique and results obtained in sternal puncture are reviewed by Andre Dreyfus in the *Concours medical*, March 29. The technique of sternal puncture is much simpler and far less likely to be followed by serious complications than is that of puncture of the spleen for blood specimens. A needle like that employed for artificial pneumothorax and provided with a mandrin, is introduced under local (ethyl chloride) anesthesia through the first portion (manubrium) of the sternum, a little to one side of the midline, and near the junction of the first and second bones of the sternum. Sufficient blood can be obtained, on withdrawing the piston of a syringe attached to the needle, to be spread on several slides for staining. The slides are fixed for ten minutes in methyl alcohol (absolute), stained by the May-Grunewald-Giemsa method for thirty to forty-five minutes and then examined with the aid of an oil immersion lens. The resultant myelogram, as it is termed, can be grouped as follows:

1 Red series. The ratio of nucleated red cells to leukocytes is as one to five, i. e., about 10,000 to 50,000. In this number of nucleated red cells there are from 3 to 5 per cent of proerythroblasts.

2 Myeloid series. Myelocytes 4 to 6 per cent, neutrophil myelocytes 30 to 35 per cent, polymorphonuclear neutrophils 25 to 30 per cent, myelocytes and polymorphonuclear eosinophils 1 to 5 per cent, myelocytes and basophil polymorphonuclears 0 to 0.5 per cent, making a total for the myeloid series of from 60 to 75 per cent.

3 Lymphoid series. Lymphocytes 20 to 30 per cent and plasmocytes 5 to 10 per cent, making a total for this series of from 20 to 35 per cent.

4 Monocytic series. Monocytes 2 to 5 per cent.

In addition, one finds a certain number of cells belonging to the reticulo-endothelial system.

With the aid of sternal puncture, the Biermer type of anemia can be immediately diagnosed by the presence of "primordial erythroblasts," a term which Dreyfus applies to the Ehrlich megaloblasts. A secondary anemia, e. g., that due to a gastric cancer, can be easily excluded.

The true aplastic anemias, in which the blood obtained by ordinary methods fails to show any evidence of regeneration, can be divided by the results of the sternal puncture method into (a) the true aplastic anemias in which there is an absence of every erythroblastic element and (b) the hypoplastic anemias much more common, in which the medulla shows evidence of erythropoiesis whereas the blood fails to show any such regenerative elements. These aplastic anemias frequently appear clinically as aleukemic leukemias and here the sternal puncture enables such a differential diagnosis to be made. In all the anemias the regeneration of the blood as the result of treatment can be followed much more accurately in a myelogram than in a hemogram.

Sternal puncture is of special value in the aleukemic leukemias, e. g., myeloma and lymphoma. It enables a diagnosis to be made of acute leukemia (lymphoid or myeloid) in cases that cannot be diagnosed by any other method. The agranulocytoses present a difficult diagnostic problem which the myelogram renders comparatively easy.

Other diseases in which sternal puncture is of great aid are atypical forms of Hodgkin's disease and the various hemorrhagic disorders.

Often cultures taken from the blood obtained by sternal puncture will be positive, whereas those obtained by the ordinary method are negative, according to Debre.

Myeloid Megakaryocytic Splenomegaly Diagnosed by Puncture of Spleen

At the May 1 meeting of the Société médicale des hôpitaux of Paris the value of puncture of the spleen in the diagnosis of diseases of the blood-forming organs was emphasized by Emile-Weil and his associates. A man, aged 54, had a splenomegaly of three years' duration. The blood examination revealed an orthochrome anemia of medium degree with a leukocytosis of 18,600, 30 per cent myelocytes, and normomegaloblastosis of 24 per cent. If the splenic puncture had not been made, the diagnosis would have been myeloid subleukemia. The puncture of the spleen and the resultant blood examination (splenogram) revealed an intense erythroblastosis and the presence of numerous megakaryocytes. Roentgen treatment of the enlarged spleen only caused the myeloid reaction to cease but had no influence on the erythroblastosis, so that a year later a splenectomy appeared to be indicated. The spleen weighed 2 Kg (4½ pounds) and showed on microscopic study a complete absence of its normal pattern. Sternal punctures before as well as after the operation revealed the absence of any medullary participation in the blood picture, hence this excludes the possibility of the diagnosis of myelogenous leukemia. The compensatory enlargement of the liver following the operation shows that it is megakaryocytic and erythroblastic, thus replacing the corresponding function of the spleen.

About twelve cases of splenomegaly of the myeloid megakaryocytic type have thus far been reported, but this case is the first to be diagnosed clinically. It is not rare. The disease is one of the spleen itself and not a systemic one like leukemia. This form of splenomegaly is due to a number of different causes, the most common being tuberculosis, which has been found in nearly half of the cases.

The Convention of German Surgeons

The Congress of German Surgeons was held in Berlin at Easter. The chairman, Professor Lexer of Munich, welcomed some 1,500 delegates to the sixtieth convention. The Deutsche Gesellschaft für Chirurgie has throughout its sixty-four years of existence faithfully reflected the scholarly endeavors of German surgical research and has advocated the closest cooperation with representative groups of other medical fields. Lexer emphasized in his opening address that successful work can be carried on only by thoroughly competent surgeons who do not restrict their activities to small subdivisions of the field. The chairman advised strongly against the surgeons splitting up into separate groups.

The Frankfurt surgeon Victor Schmieden delivered a jubilee address on the "History of Laparotomy." Schmieden designated laparotomy as the most important sphere of surgery today and the one in which the greatest measure of success has been attained. He told how the nations of remotest antiquity had some knowledge of abdominal surgery and described some of the earlier technical aids. Much that appears modern in abdominal surgical procedure is in reality old, Trendelenburg's position, for example, was described by Celsus himself. The employment of the many layered suture of the abdominal wall is likewise of antique origin. Each age thinks that it has reached the zenith of accomplishment, but if the history of

medical science is passed over in retrospect it becomes evident that the most durable progress has been made precisely in the field of abdominal surgery and that the most brilliant phase of this development occupied a relatively brief period.

H. Brandis of Freiburg-in-Breisgau spoke on operative risk and its dependence on constitutional factors arising from sympathetic nervous or metabolic disorders. The nearer the liver an operation is carried out, the greater the danger. The seriousness of any operation is heightened if hepatic function is threatened with impairment. The old idea of "operable" or "inoperable" fails to coincide with the contemporary view of what constitutes in a biologic sense an operative risk. "Inoperable" in modern parlance implies the presence of refractory disorders of the circulation or of metabolism. In many instances, however, the patient may be rendered operable by amelioration of the disordered state. Consideration of the risk entailed by operative treatment has resulted in the institution of adequate prophylactic measures and this accounts for the substantially improved chances of favorable outcome. Postoperative and circulatory disturbances, shock and embolism are now less frequent. Intervention early in the course of an illness is the best prophylactic measure against operative risks.

Discussing the treatment of cardiospasm, Prof. E. K. Frey of Düsseldorf called special attention to the fact that although purely functional disturbances do not in themselves call for surgical intervention they may develop an anatomic stenosis which can be removed only by mechanical means. In unelastic strictures dilation therapy will be unsatisfactory, and it is then that the creation of a wide passage between stomach and esophagus becomes necessary. This is better effected by a transthoracic rather than a transperitoneal approach.

Professor Guleke of Jena reported on the course of untreated carcinoma of the rectum. Most of these patients live another year subsequent to the establishment of clinical diagnosis, but as many as 90 per cent succumb within from one and one-half to two years. Case records show that the patient has usually been troubled for about a year prior to consultation. If it is also assumed that carcinoma must have been present for a considerable time before the onset of subjective symptoms, the total duration of untreated cancer of the rectum must be placed at from four to four and one-half years. Of 200 patients presenting the disease who were not subjected to radical intervention or who were considered inoperable, 7 per cent lived three more years but only 1 per cent lived five more years. Radical abdominosacral intervention entailed a mortality of 14.8 per cent, when the operation was performed in one stage; the death rate was 31.4 per cent (of thirty patients), when performed in two stages the rate was 5.9 per cent (of fifty-one patients). Hence the two-stage intervention is far and away the method of choice. Data gathered from the entire literature show a mortality of below 10 per cent from the two-stage procedure. The discussion showed that the assembly generally was in accord with Guleke's observations. Under certain circumstances caution requires that the operation shall not be performed in more than two stages.

Clairmont of Zurich submitted a paper on "Contraindications in Nonemergency Operations." He detailed the various possible types of physiologic examination employed in testing functional capacity. The physician's knowledge of pathologic anatomy frequently fails to lead to a satisfactory explanation. Operative trauma means a burden on many organs. The strain on the circulation may be psychogenically imposed prior to the operation or it may begin with narcosis. The variations in tonus and the sudden fluctuations of the blood pressure that take place under narcosis subject the circulation to a singularly heavy burden. The respiration is likewise heavily taxed and there are in addition the influences of metabolism, elevation of the diaphragm, postoperative intestinal atony and so on.

The hematopoietic mechanism demands a substantial production of new cells by the bone marrow. An attempt should therefore be made to estimate the risk entailed by nonemergency intervention in a given case and adequate preliminary treatment initiated if possible.

Schneider of Freiburg-in-Breisgau has studied the "Burden Placed on the Circulation" by the influence of surgical interventions. He is particularly concerned with the blood values (minute volume, output). The amount of blood in circulation is usually decreased by narcosis, it is increased, however, in exophthalmic goiter or thyrotoxicosis, is present as well as by surgical infection and prostatic hypertrophy. In the foregoing diseases, although the quantity of blood in circulation increases rapidly, it returns as rapidly to normal following the intervention.

Further remarks on the mortality from operations were made by Seifert of Würzburg. He has established that prognosis in cancer cases in which operative intervention is undertaken grows more unfavorable the greater the patient's age. Mortality from operations rises rapidly among women beyond the sixtieth year of life, whereas men in the same age groups appear better able to maintain their resistance. All in all, the inference would seem to be that operations for cancer on patients of any age possess an operative mortality below the average.

Payr of Leipzig supplied impressive figures on the cure of cancer by operation. Payr used as material his own operation in private practice, and the postoperative norm of time on which he based his conclusions was set at ten years. He had twenty-nine patients, originally presenting carcinoma diversely located, who had been free from recurrence of the disease for more than ten years subsequent to operation. Of these patients only a small number had received postoperative radiotherapy. König of Würzburg said he subscribed to the opinion that the number of permanent cures of cancer, especially those effected by timely use of the knife, is much greater than is generally supposed. This is of particular importance in view of the perennial rumors with regard to the incurability of cancer set on foot by persons unqualified to speak.

The next topic was the "Predispositions to and Heredity of Cancer." According to Hintze of Berlin, any predisposition can be inherited as such. A localized tendency, however, is not equivalent to a general predisposition toward tumor formation. Cancer is wont to appear in certain locales of predilection along the hair line, on the boundary between the skin and the mucous membrane, on the borders of pigmented areas. In 85 per cent of the cases, mammary carcinoma has its seat in the upper external quadrant. Almost without exception, cancer attacks only a breast that has given suck. Why the disease should originate within the respiratory, alimentary and genito-urinary tracts is difficult to explain. Carcinoma would seem to appear most frequently in places where during the period of growth, the buds of the elongated intermediate sections are present. It may be that a remnant of the originally strong tendency to grow has simply persisted. Perhaps the proximal part of the femur as the seat of sarcoma can be explained in the same manner. According to all investigators only the predisposition to cancer is inherited, not the cancer itself. Only in case of inbreeding or if both parents are cancerous is the probability that the descendants will have the disease increased above the average for the population as a whole. Prof. K. H. Bauer of Breslau, a surgeon, emphasized the difficult nature of the question of the hereditability of cancer. Under no circumstances can the results of experiments with tumors in the mouse be made applicable to man. Reliable data with regard to heritability of cancer is available only for polyposis intestinalis and xeroderma pigmentosum. All other neoplasms must be provisionally considered as nontransmissible. The entire world literature mentions only ten cases in which

each of a pair of dizygotic twins presented cancer, whereas cases of malignant growths presented by one of a pair of such twins are numerous enough. This permits the supposition that external factors assume the decisive etiologic role in cancer.

Rieder of Hamburg dealt with the status of surgery of the sympathetic nervous system. The entire sympathetic system must be thought of as forming a syncytium. Since periarterial sympathectomy involves but one part of the sympathetic network, it can never be more than partially successful. Extirpation of a ganglion never results in a permanent vascular paralysis, because of an extensive peripheral automatism, the so-called peripheral automatic vasomotor center. Recidivation after theoretically correctly performed operations is explicable as due to this peripheral automatism, that is, the operation may provide neural or humoral stimuli to the vasomotor center. The most satisfactory results are forthcoming when the procedure is used in reflex-nutritional bone disease in true Raynaud's disease, and in endarteritis obliterans. In paroxysmal tachycardia also favorable results have been reported. Hyperhidrosis and vasomotor-trophic edema are frequently benefited and abbreviated by operative treatment. There is little sense in the treatment of bone and joint tuberculosis or arthritis deformans by ganglion operation. The results of sympathetic nerve intervention in epilepsy, glaucoma, parkinsonism and atypical neuralgia are also unsatisfactory. In the discussion that followed, the Strasbourg surgeon Leriche, who is an authority in this field, emphasized that good results are obtainable in kidney disorders if the latter arise from blood perfusion disturbances due to vascular spasms. From 1,119 personally observed cases, Leriche concludes that the physiologic foundations are still wholly unknown and on this account the strictest criteria must be applied and the utmost caution exercised in the interpretation of indications. In other diseases also, sporadically successful results are observed along with the failures.

Kirschner of Heidelberg sponsored the use of electrocoagulation of the ganglion in *tic douloureux*. Of 235 patients observed by him, all but eleven were free from pain after the intervention, in those who still complained, the cause of the pain was more centrally located. In five cases a bilateral operation was performed with favorable results. Recidivation took place in 25 per cent of the patients, but after further coagulation the pain was immediately dissipated.

The Sedimentation Rate in Surgical Conditions

At a recent session of the Vienna Surgical Society, Professor Kunz spoke on the value of observing the velocity of sedimentation in the blood of surgical patients. Although in the past sixteen years more than 2,000 works have been published on this subject, the true nature of the reaction (variation in the sedimentation speed of erythrocytes) has not been determined. Apparently blood plasma is an important factor and it is believed that in certain pathologic processes substances enter the blood which accelerate the sedimentation speed in resorption of inflammatory substances, for example, or in absorption of the products of decomposition. After aseptic operations the sedimentation speed undergoes alteration in the direction of a persistent acceleration in disturbances during the curative process the return to the normal value is troubled. An acceleration is present in bone fracture cases which persists until consolidation has been effected. The sedimentation speed is of practical importance in diseases of the bones and joints as it may permit an inflammatory to be distinguished from a noninflammatory process. It is also an aid in the detection of tuberculous alterations and in the evaluation of the success of the therapeutic measures initiated. It helps the physician

to determine whether or not a diseased joint may again be permitted to exercise its function or an orthopedic intervention for the removal of a defect be performed. Likewise in the question of whether or not a case of pulmonary tuberculosis should receive surgical treatment the sedimentation speed provides valuable indications. It has a prognostic importance after radical operations on malignant tumors, if it resumes the normal value especially quickly and remains normal thereafter, recovery is indicated, but a renewed increase points to a relapse or metastases. In abdominal surgery the sedimentation speed helps the physician to distinguish between an adnexitis and an acute appendicitis, for example, it also serves as a good diagnostic aid in the latter disease in combination with the white blood picture. The sedimentation speed is normal in simple acute appendicitis and the leukocyte count only a trifle above normal, but in phlegmonous appendicitis, although the sedimentation speed remains normal, the leukocyte values are high. An accelerated sedimentation speed becomes first evident in perforation, the abdominal phenomena are thus not fulminant. But should the sedimentation speed show considerable increase, this speaks against an acute appendicitis. The sedimentation speed can be of value also in the recognition of the various forms of cholelithiasis and its complications. The sedimentation speed is normal in stomach and duodenal ulcer and remains so during the first few hours following perforation. Accordingly, the accelerated sedimentation speed in a perforation peritonitis indicates an inflammation of the perforated organ or its surroundings which has existed for a long while previously, while the normal sedimentation speed is evidence of the perforation of an ulceration.

Sigmund Freud's Anniversary

On the eightieth birthday of Prof Sigmund Freud, by far the best known Austrian physician of recent decades, many celebrations were held in Vienna, none of which were attended by Freud himself. Since he underwent a serious operation (supramaxillary resection) Professor Freud has been confined to his bedroom. Both the Vienna Society of Physicians and the Psychiatric-Neurologic Association held extraordinary sessions in his honor despite the fact that the Freudian doctrines were at one time categorically rejected within both these organizations. As a sequel of these controversies Freud has not attended a single meeting of either group in fifty years. The government could not overlook the significance of this man, despite his Jewish origin. Freud received official congratulations from all over the world. Only the German reich maintained conspicuous silence—for obvious reasons. An interesting series of lectures was delivered by Nobel prize winner Thomas Mann, one of the greatest of living poets and himself an émigré from Germany, on "Freud and the Future." Mann pictures Freud as "the pathfinder of a new humanity," as one who points the way out of darkness into the light that shall dispel hatred and fear, he sees in Freud the prophet of a bright and joyous era of peace on earth. The following incident illustrates the difficulties with which Freud at first had to contend. When in 1886 he made known his theories to the Society of Physicians in Vienna and spoke of such things as hysteria in males, the meaning of dreams and the suggestive production of hysterical paralysis, the leading Viennese neurologists of that time declared his words unworthy of belief and beyond the pale of discussion. Freud was accordingly refused membership in the Institute of Cerebral Anatomy (Meynert). And when at a later date Freud had proved his theory of infantile sexuality which is the most important pillar in the whole Freudian structure his teaching was completely rejected both by pediatricians and by the church. Only long afterward did his doctrine first encounter recognition. Freud, imperturbable lives and works on despite his eighty years and he is not to be induced into making public appearances.

Congress of Catholic Physicians

The second International Congress of Catholic Physicians, in which 500 doctors from twelve countries participated was held at Vienna during Easter week of this year. The proceedings were confined to two principal topics: the first, "Eugenics and Sterilization", the second, "Medical Missionary Activity."

Death of Prof. Ludwig Braun

The distinguished cardiologist Ludwig Braun died recently of an infection, aged 70. Braun took his degree at Vienna. His original intention was to be a surgeon but he was forced to abandon this plan because of a hypersensitivity to iodoform, a substance much used at the time. Braun then turned to internal medicine. In his work on cardiac action he was a pioneer in using motion pictures as an aid in medical research. Other investigations, on the effects of digitalis and on arteriosclerosis, formed the material of a remarkable book on heart disease, which is still considered excellent. Braun was a master research scholar in the field of aortic and cardiac syphilis but his greatest achievement was the discovery of the interrelation of the kidneys and high blood pressure. During the last ten years he had been much occupied with this problem. Wide notice was accorded his monograph on the heart and fear (1932). Braun did much to stimulate experimental cardiac research. In 1910 he became both professor and director of the section of internal medicine at the Jewish Hospital, Vienna, and was much sought out by doctors and patients as a distinguished teacher and brilliant diagnostician. Also as a philanthropist and sociologist Braun rendered notable services.

Sweeping Changes in the Law on Abortion and Divorce

The Soviet Government published May 26 a proposed bill which would make artificial abortion illegal and provide help to pregnant women, enlarge the lying-in homes, the kindergartens and public nurseries, and make amendments to the divorce law. The immense importance of this bill was the reason why the government first sanctioned a wide discussion by the entire population in the press at meetings, and in scientific societies. After this discussion is finished, the suggested changes received will be considered, and the bill will become a law.

The history of legalized abortions in our country begins with Nov. 18, 1920, when the government published a decree permitting artificial abortions for medical and social indications. Any woman who wanted to end her pregnancy could enter a special medical establishment or lying-in house, where abortion was performed. The improved conscience of the people as well as improvement in the cultural and material level has increased the birth rate and brought on a marked desire to discontinue abortions. Taking in account all of the facts mentioned, the Central Executive Committee of the Union of Socialist Soviet Republics found it possible to propose this bill to the people. It would prohibit abortion in hospitals, clinics, ambulances, private houses and so on and allow the operation only when the pregnancy would endanger the woman's life. When that reason for an abortion does not exist the physician operator will be punished with two years in prison. If the abortion is made by a person without special medical education he is imprisoned three or more years. Women breaking this law are indictable to public censure and on repeated violation to a fine of 300 rubles.

To make the family more stable and to eliminate frivolous marriages both parties must be present in the registry office in cases of divorce. The divorce must be registered in both passports and the cost is raised to 50 rubles for the first one.

150 for the second and 300 for the next. Alimony must be recovered for the children's maintenance after divorce, one-third of the respondent's salary for one child, a half for two children and 60 per cent for three and more.

The government proposes to improve the material status of mothers. Instead of 32 rubles as received now for a dowry for the new-born there will be given a dowry of 45 rubles and 10 rubles monthly instead of 5 for feeding the infant. To mothers having more than seven children, the government will pay after the birth of each child 2,000 rubles for five years to mothers having eleven children, 5,000 rubles after each addi-

Distribution of Appropriations

| | |
|--|-----------------------------|
| City lying in beds | 22.2 million rubles |
| Country lying in beds | 23.8 million rubles |
| Public nurseries | 230.0 million rubles |
| Kindergartens | 221.0 million rubles |
| Children's milk kitchens | 9.0 million rubles |
| Total | 506.0 million rubles |
| Except for | |
| Erection and maintenance of public nurseries | 11.8 million rubles |
| Improvement of kindergartens | 30.8 million rubles |
| New staff education | 50.0 million rubles |

tional birth, and beginning with the second year, an annual help of 3,000 rubles extra during the four years after the child's birth.

By Jan. 1, 1939, there must be organized 11,000 new lying-in beds in cities and 32,000 in country districts, half of them in obstetric departments of country hospitals and the second half in newly established collective farm lying-in houses. The number of beds in public nurseries must reach 800,000 in towns and 4,500,000 in country districts by the same time.

Fifteen million rubles extra will be devoted this year especially to training supplementary medical personnel.

The number of places in city kindergartens will reach 2,100,000 by the end of 1938, instead of 700,000 as at present.

In country districts there will be organized preschool groups for 23,000,000 children. This year 35,000,000 additional rubles for instructing new teachers will be assigned. To realize these measures the government will give this year, besides 1,881.3 million rubles for social insurance, 672.8 million of rubles. They will be divided as shown in the table.

All the foregoing measures must be realized during the next two and a half years.

A Decrease in Syphilis

Syphilis has been a widespread disease in Russia. Dr. Khym studied syphilis at the end of the last century in the Voronezh department in central Russia, where a twenty bed hospital for antisyphilitic treatment was situated. His figures show that from 1889 to 1893 a total of 4,109 patients—of whom 516 were children—passed through the clinic. About one third of the cases in the primary stage.

Dozent S. Galperin repeated Khym's work for the period from 1929 to 1933 in the same place. He registered only 143 cases of syphilis. These figures, relating to one of the most populous regions of the country, demonstrate that there has been a sharp decrease in the incidence of syphilis.

Professor Honored for Popularizing Anesthesia During Labor

Previous to 1934, anesthesia during delivery was used but rarely in the Soviet Union. Through the initiative of Prof. A. J. Lourje of Sverdlovsk, anesthesia during childbirth now is widely used. Professor Lourje has been honored for introducing and popularizing a safe method of anesthesia during labor with the order of Lenin—the highest reward in the Union of Socialist Soviet Republics. It is believed that not less than 300,000 women will be thus relieved of labor pains this year.

Marriages

CLARENCE EDGAR YOUNT JR, Prescott, Ariz, to DR FLORENCE HEARN BROOKHART of Washington Iowa, June 22

JOSEPH WOODS BRUNSON, Chester S C, to Miss Charlotte BOYKIN SALMONO of Camden, June 6

TREVOR DOUGLAS ABEL, Columbia, S C, to Miss Louise Fleming at Charlotte, N C, May 28

JOHN R BENDER Jacksonville, N C, to Miss Louise L Zimmerman of Lexington, June 20

CLARK E BAKER to Miss Polly Heaton, both of Marion Ill, in Beaumont, Texas, May 12

MALCOLM HUGH MCBRYDE to Miss Margaret Whitlock both of Milton, N C, May 23

HYMAN LEWIS BERSON to Miss Judith Hilda Lichtenstein both of Brooklyn, June 30

E. RAYMOND AMBLER JR, Abington, Pa, to Miss Jean Richardson Fagans, June 13

RICHARD F BOYD, Cimarron, Kan to Miss Kathleen Ragan in Chicago in June.

Deaths

Joseph Patten Wales of Wilmington, Del, University of Pennsylvania Department of Medicine Philadelphia, 1898, past president of the Medical Society of Delaware and the Newcastle County Medical Society, for several years a member of the state board of health, at various times surgeon to the police department, director of the city department of public safety aged 62 on the staff of the Delaware Hospital, where he died April 16, of pneumonia

Paul Maxwell N Kyle of Major M C, U S Army Denver University of Maryland School of Medicine Baltimore, 1916, served during the World War, entered the Medical Corps of the U S Army as a lieutenant in 1917 and in 1929 was appointed a major, aged 45, was stationed at the Fitzsimons General Hospital, where he died, May 1 of pulmonary tuberculosis and tuberculous meningitis

Aden Cobbs Vickrey, St. Louis, Washington University School of Medicine, St. Louis, 1911 member of the Missouri State Medical Association at one time superintendent of the State Hospital, number 2, St. Joseph, Mo., and assistant superintendent of the City Sanitarium for several years connected with the U S Public Health Service, aged 50 died April 10, of burns received in a fire

Milton Thomashefsky, Brooklyn Columbia University College of Physicians and Surgeons, New York, 1921 member of the Medical Society of the State of New York, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, associate, ear, nose and throat, Jewish and Greenpoint hospitals, aged 38 died May 15

William Armstrong Byrnes of A Surg, Lieut, U S Navy, retired, Minneapolis, University of Illinois College of Medicine Chicago 1917, entered the navy in 1917 and retired in 1922 for incapacity resulting from an incident of service advanced on retired list, served during the World War aged 45 died in May in San Diego, Calif

William Bartholomew Wanner, Wimbledon, N D Rush Medical College, Chicago, 1893, member of the North Dakota State Medical Association, past president of the Sheyenne Valley District Medical Society, served during the World War aged 68 died April 18, in the Trinity Hospital Jamestown of arteriosclerosis

Francisco Javier Rodriguez Mendoza, Cartagena Colombia South America, University of Pennsylvania Department of Medicine, Philadelphia 1930, professor of clinical surgery and anatomy and operative medicine at the University of Cartagena School of Medicine, aged 30 died April 3 of pulmonary tuberculosis

Herbert Booth Woodard of Chicago, Hahnenmann Medical College and Hospital Chicago 1897, also a resident of Hinsdale Ill served during the World War fellow of the American College of Surgeons aged 66, on the staff of the Hinsdale Sanitarium and Hospital where he died May 25 of thrombosis

Frederick William Boyd, Montgomery, Ala, University of Alabama Medical Department Mobile 1906 served during

the World War, physician in charge of the Kilby Prison Hospital, aged 56, died, May 1, in a hospital at Talladega, of an accidental gunshot wound received while cleaning a pistol

Patrick Joseph Byrne, Syracuse N Y, Bellevue Hospital Medical College, New York 1893 member of the Medical Society of the State of New York, on the staff of the Crouse-Irving Hospital and St Mary's Maternity Hospital and Infants Home, aged 75, died, May 7, of coronary thrombosis

David Kaplan of Oak Park, Ill Rush Medical College Chicago, 1919, for many years cardiologist to the Veterans Administration Facility, Hines, Ill aged 41, recently appointed chief cardiologist to the Veterans Administration Facility New York, where he died, April 17 of heart disease

Gregory E Ehrenburg, Spivak, Colo Voronej Government University Faculty of Medicine, Voronej, Russia 1899 member of the Colorado State Medical Society on the staff of the Sanatorium of the Jewish Consumptives Relief Society aged 62, died May 10 of cerebral hemorrhage

Ernest Howard Lines, New York College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1886, served during the World War, formerly chief medical director of the New York Life Insurance Company aged 76, died, April 17, in Topsfield Mass

W Theodore Waas, Fernandina Fla Tulane University of Louisiana Medical Department, New Orleans 1894 formerly a druggist, for many years a member and president of the city council, local surgeon to the Seaboard Air Line Railway and county physician, aged 70, died April 23

Edwin Erastus Clark, Knoxville Pa, College of Physicians and Surgeons, Baltimore, 1893 member of the Medical Society of the State of Pennsylvania, aged 69 died, May 12 in the Arnot-Ogden Hospital, Elmira N Y, of septicemia which developed following a prick by a thorn

William Edward Croxton of West Point Va, Medical College of Virginia, Richmond, 1904, during the World War was medical examiner of the county exemption board, for many years chairman of the school board aged 53, died, May 9, in a hospital at Richmond, of pneumonia

Dock Long, Duncan, Okla, Southern Medical College Atlanta Ga, 1882 member of the Oklahoma State Medical Association, health superintendent of Stephens County aged 75, died, May 21, in the Wesley Hospital, Oklahoma City, of mastoiditis and cerebral hemorrhage

Henry Kuhl Dillard of Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1902 served during the World War, assistant medical director of the Penn Mutual Life Insurance Company aged 59, died, May 17, in Asheville, N C. of tuberculosis

Aaron Longstreet Stillwell of Somerville, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York 1889 past president of the board of health aged 71 on the staff of the Somerset Hospital where he died April 16 of myocarditis

Wesley Herbert Secord, Winnipeg Manit Canada McGill University Faculty of Medicine Montreal Que 1903 past president of the Council of the College of Physicians and Surgeons of Manitoba aged 53, died May 13 of spongio blastoma multiforme

Harvey Willard Tupper, Harvey Ill, University of Illinois College of Medicine, Chicago, 1913, served during the World War aged 47 on the associated staff of the Ingalls Memorial Hospital where he died April 18 of carcinoma of the prostate

Jacob W Rothacher, Detroit Detroit College of Medicine 1897 at one time a druggist, formerly county coroner and city physician, for many years on the staff of St Mary's Hospital aged 65, died suddenly April 21, of angina pectoris and diabetes mellitus

Joseph Leander Roseborough, Senatobia, Miss, Vanderbilt University School of Medicine, Nashville Tenn, 1877 for fifty years physician and surgeon to the Illinois Central Railroad, aged 81 died April 22 in the Baptist Hospital Memphis, Tenn.

John William Dalrymple, Hackettstown, N J College of Physicians and Surgeons Medical Department of Columbia College New York 1877, aged 81 died, May 1, in the Warren Hospital, Phillipsburg, of diabetes mellitus and uremia

Erwin Leon Stafford, Chestertown, N Y, University of Vermont College of Medicine Burlington 1883, aged 84 died April 13, in the Moses-Ludington Hospital Ticonderoga, of a self inflicted bullet wound and cerebral hemorrhage

Clayton H. Charles, Milwaukee, Hahnemann Medical College and Hospital, Chicago, 1902, veteran of the Spanish-American War, aged 57, died, May 3, in the Veterans' Administration Facility, of pneumonia.

John Hunter Carradine, Lawton, Fla., Tulane University of Louisiana Medical Department, New Orleans 1890, aged 71, died, May 1, in St. Luke's Hospital at Jacksonville, of arteriosclerosis and bronchopneumonia.

William Goldsmith MacLachlan, McFarland, Wis., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890, member of the State Medical Society of Wisconsin, aged 86, died, April 10.

John Joseph Stanton, Philadelphia, Jefferson Medical College of Philadelphia 1903, formerly on the staffs of St. Joseph's and St. Agnes hospitals, aged 56, died, April 15, of coronary occlusion.

John Webster Snow, Helena, Ala., Birmingham Medical College, 1909, member of the Medical Association of the State of Alabama, aged 54, died, April 19, of appendicitis and diabetes mellitus.

Joeday N. Goodwin, McAllen, Texas (registered by Texas State Board of Medical Examiners under the Act of 1907), aged 63, died, May 5, in McAllen Municipal Hospital, of mesenteric thrombosis.

Katharine Annabelle Hathaway Salmon, Syracuse, N. Y., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887, died, April 15, of intestinal obstruction and arteriosclerosis.

Russell Truitt, Southwick, Idaho, Eclectic Medical Institute, Cincinnati, 1877, member of the Idaho State Medical Association, aged 83, died, April 19, in Lewiston, of chronic myocarditis.

Albert Hamilton Taft, Hillsboro, N. H., McGill University Faculty of Medicine, 1932, member of the New Hampshire Medical Society, aged 29, died, April 21, in Concord of septic sore throat.

Royal Scott Stuckey, Maywood, Neb., University of Nebraska College of Medicine, Omaha, 1903, aged 62, died, April 7, in St. Catherine of Siena Hospital, McCook, of nephritis.

Neill Malcolm Watson, Red Lake Falls, Minn., McGill University Faculty of Medicine, Montreal, Que., Canada, 1891, aged 70, died, April 6, of coronary thrombosis and diabetes mellitus.

Daniel Wesley Le Grand, East St. Louis, Ill., Washington University School of Medicine, St. Louis 1901, member of the Illinois State Medical Society, aged 66, died, April 30, of heart disease.

Charles Gustavus Morris, Battle Creek, Mich., Detroit College of Medicine 1914, member of the Michigan State Medical Society, aged 51, died suddenly, April 29, of heart disease.

James Francis Kearney, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, aged 55, died, April 9, of coronary occlusion.

Otto Klietsch, San Diego, Calif., Hessische Ludwigs-Universität Medizinische Fakultät, Giessen, Hesse, Germany, 1886, aged 75, died, April 20, of carcinoma of the rectum.

Henry William Schmidt, Chelsea, Mich., University of Michigan Department of Medicine, Ann Arbor, 1888, aged 71, was killed, April 5, in an automobile accident.

Philip Louis Kessler, Finchville, Ky., Louisville Medical College, 1900, aged 56, died, April 12, in Simpsonville, of coronary thrombosis and chronic arthritis.

Anna Rebecca Cooper, Chicago, Cleveland Medical College 1895, aged 65, died, May 2, in the Provident Hospital, of coronary occlusion and pulmonary infarct.

Shedrick Le Roy Morris, Atlantic City, N. J., Howard University College of Medicine, Washington, D. C. 1895, aged 71, died, April 26, of myocarditis.

William Arthur Schlesinger, Cleveland Heights, Ohio, Western Reserve University Medical Department, Cleveland 1904, aged 56, died, April 15.

Clement V. Marmaduke, Pueblo, Colo., Northwestern University Medical School, Chicago 1896, aged 68, died, April 14, of pneumonia.

Joseph L. Korzen, Berwyn, Ill., Chicago College of Medicine and Surgery 1917, aged 49, died, May 6, of coronary thrombosis.

Hugh A. Jones, St. Louis, Missouri Medical College, St. Louis 1886, aged 70, died, April 14, of pneumonia.

Bureau of Investigation

SNYDER PRODUCTS COMPANY, ETC.

A Chicago Outfit Declared a Fraud

Mail order quacks usually operate under a variety of high sounding names. When they have "milked" a victim dry under one firm name, they can later solicit him under another name (and perhaps from a slightly different address), so that he will not suspect that all the "come-on" stuff emanated from the same source. Recently the Post Office Department at Washington issued a fraud order against the Snyder concern, operating under the various titles Snyder Products Company, Snyder Tablet Company, Virginia Walker, Order Department, Virginia Walker, D. Ph., Women's Department, Julia Sincere, Women's Department, Indian Herb Gardens, E. E. Schneider, The Herb Medicine Man, The Vita-Tone Company, O. J. Medical Company, and their officers and agents as such.

Under these diversified names, the several companies listed, all owned and controlled by one Ernest E. Schneider, offered for sale through the mails an extensive array of alleged remedies. Several were of the "monthly regulator" or "delayed period" type, but the majority were nostrums for innumerable ailments, including tablets for kidney and bladder troubles, nervous disorders, restoring lost manhood and lost womanhood, or what have you.

I Reduced 70 lbs.

You, Too, Can Have a Charming, Graceful Figure

Many women report the loss of as much as 5 lbs. in ONE WEEK. Safely without teas, dangerous drugs, dopes or chemicals without strenuous exercising or starvation dieting. Snyder's Anti-Fat Tablets are a SAFE HARMLESS EFFECTIVE compound does not leave a flabby skin. **SEND NO MONEY** Just pay postman when delivered.

SEND NO MONEY

GUARANTEED

SNYDER PRODUCTS CO., 1434 N. Wells St., Dept. 350-U Chicago

When Answering Advertisements Please Mention Romantic Stories

Among the encyclopedic list of "patent medicines" was the ubiquitous fat cure, 'Snyder's Anti-Fat Tablets.' Like most obesity-cure copy, the 'come-on' was the picture of a damsel, clad in a bathing suit and displaying a finely proportioned figure.

The advertising lure read

I Reduced 70 lbs.

You too can have a charming graceful figure.

Many women report the loss of as much as 5 lbs. in ONE WEEK! Safely without teas, dangerous drugs, dopes or chemicals without strenuous exercising or starvation dieting. Snyder's Anti-Fat Tablets are a SAFE HARMLESS EFFECTIVE compound does not leave a flabby skin. **SEND NO MONEY** Just pay postman when delivered.

The obese who succumbed to the S. P. Anti-Fat pharascology and wrote to the company received a large, crudely illustrated circular depicting a misshapen, overweight female designated "Hypothetical Ethel" together with other illustrations purporting to show the same person reduced to an ideal figure by the use of Snyder's Anti-Fat Tablets.

The circular contained numerous representations of the marvels accomplished by this nostrum.

Why not rid yourself of cruel, Life-Shortening Fat? Now that at last it can be DONE. SAFE. Harmless. Leaves no wrinkled skin after reductions. Triumph of Medical and Pharmaceutical Science.

As a result of the advertising ballyhoo, the Snyder outfit and associated concerns received between eight hundred and one thousand letters a day, and filled between seven and eight hundred orders. The gross income for 1934 was \$87,000 which peaks eloquently for the gullibility of human nature.

Don't be discouraged or alarmed because nature fails you. You can now depend on this wonderful new S. P. Periodic Relief Compound.

Double X\ Strength (Pills) often successfully relieves some longest overdue, unusual discouraging unnatural suppressed periods generally very quickly. Some say magic like quick in action without danger pain or inconvenience. Rely on this new wonderful Relief Compound

Copy appeal, while representing the stuff to relieve irregular or delayed menstruation due to "cold, exposure to inclement weather, wet feet violent shock or other like causes," obviously winks the other eye to give the impression that the product is an effective abortifacient when it states "We do not maintain a purchasers' correspondence department. Hence we cannot answer personal letters or unethical questions. Women are quick to understand the real purposes of Snyder Products."

The "Snyder's S P Tablets Prescription O J O XX" was shown by government analysis to contain a fraction of a grain of ferric carbonate per tablet together with potassium sulfate indicating a mixture similar to Bland's mass, also emodin-bearing plant extractives but no alom or alkaloids.

Other Snyder periodic pills declared fraudulent by the Post Office Department included "O J O Relief Compound," "S P Relief Compound and S P Treatment," "S P Snyder's Tablets Combination No XXX" and "S P Snyder's Tablets No XX." The fraud order debarring the Snyder (Schneider) interests from the mails was issued in April, 1936.

Correspondence

THE USE OF DESICCATED THYROID

To the Editor—The presentation of Dr John M Berkman on "Low Basal Metabolic Rate and the Use of Desiccated Thyroid" (THE JOURNAL, June 13) is interesting not alone for what it says but also for what it implies. Are we to understand that no clinical indications arise for the use of thyroid in conditions not accompanied by low metabolic rates? If so, is one to understand further that only the thyroxine principle in desiccated thyroid is the therapeutically active unit in the complex mixture called desiccated thyroid? What does the author mean by a difference in potency of different preparations of desiccated thyroid, assuming, as one must, that the iodine content of all offered desiccated products meets the U S P requirements? I trust that the author, in asserting this difference in potency, had no reference to the fact that one manufacturer persists in labeling his product on a basis of the weight of the fresh gland, as against the general procedure of other manufacturers to label their products on a basis of the weight of the dehydrated material. There is a feeling among many competent clinicians that thyroid can be and is effectively used in conditions not accompanied by a low metabolic rate and that the present state of knowledge of thyroid function does not permit the categorical judgment that thyroid function is synonymous with thyroxine activity.

HERMAN SHARLIT, M D, New York.

[Dr Sharlit's comments were referred to Dr Berkman, who replies.]

To the Editor—My intention was not to imply but to state directly that in my opinion there are no indications for the prolonged use of desiccated thyroid except in the presence of a definitely depressed basal metabolic rate. However, this statement, or implication if you will was qualified by a paragraph on page 2045 as follows: "As a general rule one does not expect favorable results from elevation of the metabolic rate unless that rate is in the region of minus 16 per cent or lower and when such a rate is associated with definite symptoms the most significant of which are fatigue and intolerance to cold." This paragraph of course is in particular reference to the group of cases in which there is a low basal metabolic rate without myxedema. Of course the foregoing statements

are made on the assumption that the basal metabolic rate determinations have been accurate and truly represent the rate of metabolism in the individual patient.

From a chemical standpoint, desiccated thyroid is a complex mixture. However, from a practical standpoint thyroxine appears to be the only therapeutically active ingredient. This is strongly suggested by the fact that in the treatment of myxedema pure crystalline thyroxine is just as effective as desiccated thyroid and completely eradicates all the symptoms of the condition.

Thirdly, it was not my intention to imply that any one preparation of desiccated thyroid was more efficacious than another but to suggest that adherence to one brand of desiccated thyroid allows one to become accustomed to the effect of the dosage. As to the variance in potency, Gutman, Benedict and Palmer analyzed the thyroxine content of various thyroid preparations on the market and found a variation between the highest and the lowest of 259 per cent. Means, Lerman and Salter assayed the effect of various commercial preparations of thyroid gland on myxedematous patients and found that the calorogenic action depended on the total organic iodine content rather than on the thyroxine-iodine content.

JOHN M BERKMAN, M D, Rochester, Minn.

VARIATION IN BILE PRESSURE IN HUMAN BILIARY TRACT

To the Editor—May we call attention to the erroneous conclusions regarding biliary tract pressure implied by the paper entitled "Observations on the Variation in Bile Pressure in the Human Biliary Tract" by Harold A Kipp in THE JOURNAL, June 27, page 2223.

Biliary tract pressure is measured either against the effective resistance of the Oddi sphincter while the bile is being secreted by the liver (in which case there is no flow through the sphincter) or maximally at the level at which the sphincter just ceases to be effective. If the sphincter is closed completely (nonfunctioning) and a side arm is added to the biliary system (stomach cholecystogastrostomy), the system must include the stomach, and the pressure in the biliary radicles depends on the height of fluid level in the stomach over the point of reference in the biliary tract, and also on the gastric tonicity. This is admirably illustrated in the author's figure 2, although in the paper it is given scant consideration. Any readings obtained in such a system cannot be considered to be biliary tract pressures, but biliary tract plus intragastric pressures, and explanations of variations in readings must take into consideration factors which affect gastric pressure, such as recumbency, standing and coughing. Thus, from this case no conclusions can be drawn concerning biliary tract pressure or factors controlling it in human beings.

Furthermore, by the method employed in this case, even if the sphincter were normal and no cholecystogastrostomy had been performed, pressure readings would have been of doubtful significance since the position of the sphincter was merely guessed at. Similar objection may be raised to the method employed by McGowan, Butsch and Walters in their paper on

Pressure in the Common Bile Duct of Man in the same issue of THE JOURNAL, since they frankly measured pressure only from the point of emergence of the tube from the skin. A method for accurately measuring maximum biliary tract pressure in man at the sphincter of Oddi has been described (Koster, Harry, Shapiro, Arthur and Lerner, Harry, On the Rate of Secretion of Bile, *Am J Physiol* 115 23 [March] 1936).

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

UNDULANT FEVER

To the Editor—A man aged 42 has been sick for the past three months. The history and clinical course are compatible with undulant fever except that repeated agglutination tests have been negative. Recently an intradermal skin test of 1:500 dilution of a stock vaccine containing 2,000 million each of *Brucella abortus* and *Brucella melitensis* gave a mildly positive reaction with a zone of erythema 1 cm in diameter and slight swelling. It also caused a rise of temperature to 99 F and a rise of pulse to 110 for the first time in three weeks. How much reliance may be placed on such a skin test? I would appreciate references to recent good literature on the subject. Please omit name.

M D Massachusetts

ANSWER—Burnet, Carpenter, Simpson and others have found that a small proportion of individuals with brucellosis (undulant fever) from whose blood *Brucella* may be recovered, fail to develop specific serum agglutinins. The intradermal test utilizing heat-killed or formaldehyde killed *Brucella* organisms as antigen, appears to be of value in identifying individuals who have acquired cutaneous sensitiveness after the invasion of tissues by living *Brucella* organisms. The endermic reaction is of value in the diagnosis of brucellosis, particularly in cases in which no agglutinins for *Brucella* are found in the blood serum after repeated testing, and in those in which *Brucella* cannot be grown on culture of the blood, urine, stools or bile. The skin test is also of value in those cases in which the agglutination reaction is doubtfully positive in low titer (from 1:10 to 1:100). Bacterial filtrates have been utilized for the intradermal test but heat-killed bacterial suspensions seem to have a more specific action. The *Brucella melitensis* (abortus) vaccine, which is used in the therapy of brucellosis, may be utilized for the skin test. Because of the extreme sensitiveness of some persons to the intradermal injection of killed *Brucella* organisms, it is desirable to reduce the bacterial content of the test dose by diluting 0.1 cc of the vaccine with 0.4 cc of sterile physiologic solution of sodium chloride. The intradermal test is made with 0.1 cc of the diluted suspension producing a wheal about 5 mm in diameter. A positive reaction will develop in from twelve to forty-eight hours at the site of the injection. A positive test is characterized by the gradual development of an indurated reddish area usually from 3 to 5 cm in diameter. The induration usually persists for several days. A faint transient pink reaction without induration should probably be regarded as a negative test. In particularly sensitized individuals a systemic reaction may occur following the injection of the skin test antigen. In interpreting the results of such cutaneous tests consideration must be given to the fact that presumably normal persons may develop cutaneous hypersensitiveness without symptoms of illness as the result of previous subclinical (asymptomatic) *Brucella* infection. Consideration must also be given to the fact that cutaneous sensitiveness remains after recovery from brucellosis. Thus, a person who has cutaneous hypersensitiveness to *Brucella* antigen may be suffering from some other disease at the time the test is made. A positive skin test in such a case may be merely the result of asymptomatic or symptomatic brucellosis acquired some months or years previously. In such cases, due regard should be given to the clinical symptomatology. If repeated agglutination tests are negative and if the intradermal skin test is negative it is quite unlikely that the patient has or has had brucellosis.

The following recent reports describing the intradermal test as an aid in the diagnosis of undulant fever, may be consulted:

PERSISTENT FISSURE OF TONGUE

To the Editor—A woman aged 35 divorced mother of one child 13 years of age complains of fissures of the upper surface and the edges of the tongue for the past four months. The tongue feels tender at times and varies in appearance from day to day and even from morning to night. The fissures vary in size and depth from time to time and do not appear to be affected by treatments with 10 to 20 per cent silver nitrate tannic acid in glycerin boric acid physiologic solution of sodium chloride sodium perborate dilute hydrochloric acid by mouth cod liver oil intramuscular injections of hydrochloric acid and a strict diet eliminating salt spices condiments and lemons of which she is fond and used to eat in large quantities. She used sodium perborate as a routine before the onset of the soreness. The patient is active. Her home surroundings are all but pleasant which results in her vomiting quite frequently whatever she may eat or drink even if it is water. She has never smoked and has not indulged in alcohol on account of its having been the main cause for her divorce. Her teeth are in excellent condition with no rough surfaces evident. In spite of all forms of diet and exercises she suffers from chronic constipation, which is being corrected by the use of agarol or caroid and bile salts. Examinations by different physicians agree with my observation that there is no apparent organic disorder. The blood pressure is 110 systolic 70 diastolic pulse 80 respiration 18 20 temperature normal weight between 110 and 120 pounds (50 and 54 Kg). The patient gained 10 pounds (4.5 Kg) by using cod liver oil and intramuscular injections of hydrochloric acid. Examination of the blood reveals red blood cells 4,500,000 white blood cells 8,000 and hemoglobin 80 per cent. Smears from the tongue and gums are negative for Vincent's infection. The Wassermann reaction is negative. I should like to know what condition this is and the possibility of its being allergic. The patient uses Dorothy Gray cosmetics and Roux shampoo tint made by Roux Laboratories 9 East Forty Fifth Street New York. Is Roux tint harmless? Please advise as to a working diagnosis and modes of treatment. Please omit name.

M D Texas

ANSWER—It is impossible to diagnose the nature of the disorder from this description. Certainly, pernicious anemia should be ruled out. Even though the blood count is normal a gastric analysis should be made to see if there is sufficient hydrochloric acid. An avitaminosis should also be considered and a diet rich in vitamins should be tried. An allergic condition is also possible. Canker sores have been found to be due to allergy in many cases by W L Beecher. Beecher and others believe that ulcers may be due to allergy. He believes that the allergic reactions cause a lessened resistance to digestive ferments and that ferment action produces the actual ulcer. The persistence of the allergy prevents healing and a recurrent allergic reaction may account for seasonal incidence of ulcers.

Since the tongue condition has lasted four months, a work up from the allergic point of view is indicated. This will include a careful history of possible causative foods and complete skin tests for foods. If positive skin tests are found the foods should be removed from the diet for a trial period of about two weeks. If tests are negative, elimination diets should be tried successfully for periods of a week. One class of food may be removed at a time. Since nuts, spices and chocolate (cocoa) are particularly apt to cause symptoms in the mouth these foods should be eliminated at once.

It is not likely that cosmetics play a part here as there is lack of contact.

PARALYSIS AFTER SPINAL ANESTHESIA

To the Editor—Are there any recorded cases of hemiparalysis with loss of sphincters following a spinal anesthesia? If so is the lesion permanent? Please omit name.

M D South Dakota

ANSWER—There are reports in the literature of paralysis and of loss of control of the sphincters following spinal anesthesia. In some cases the symptoms were transient in others they were prolonged, in some the outcome was fatal. Paralysis affecting the legs and the anal and vesical sphincters occurred in two of the 924 cases reported by Bedeschi in which spinal anesthesia with amylolacine hydrochloride B P 254 ("stovaine") was employed (Bedeschi P. Considerazioni sopra 924 casi di rachistovainizzazione, *Gazz d osp* 34 249 [Feb] 1913). The paralysis of the sphincters subsided after ten days in one case and after thirty-five days in the other. In the latter case cystitis was present, and severe decubitus but the patients were able to stand and to walk, but disturbances of great weakness in the legs, and sensory

Silva reported a case of permanent paralysis of the bladder and rectum after removal of an inguinal lymph node under intraspinal anesthesia (Silva Castro B. Effects of Intraspinal Anesthesia. *Arch de med de Pernambuco* 1 47 [Feb] 1925). A case of left-sided hemiplegia following spinal anesthesia which cleared up within a month under symptomatic treatment was reported by R Dassen (Sindrome piramidal consecutivo a una raquianestesia. *Semana med* 1 1145 [April 18] 1935).

Zahradnicky observed 280 cases of paresis of the lower extremities and anal sphincter in a series of 667 cases in which procaine hydrochloride in combination with epinephrine was used to produce spinal anesthesia (Zahradnicky Ueber die Erfolge der Medullaranästhesie, speziell bei Laparotomien, *Arch f klin Chir* 89 371, 1909). These symptoms were only temporary, however, and were without unfavorable after-effects. Steuernagel had three cases in which there was slight paresis in one or both legs and sensory disturbances. In two of these cases, conditions promptly returned to normal under electrical treatment, but in the third case there was evidence of grave organic injury from the spinal anesthesia, weakness and pains in the legs, sensory disturbances, and considerable paresis of the right leg. The symptoms gradually subsided by the end of the third month, when it was found that a purely hysterical disturbance had succeeded the organic disturbances (Steuernagel, W Erfahrungen mit der Lumbalanästhesie, *Monatsschr f Geburtsh u Gynäk* 34 702 [Dec.] 1911).

Violet and Fisher collected reports of 30,000 gynecologic cases from the literature in which spinal anesthesia was used. Paralysis of the legs or sphincters developed in sixteen cases, generally subsiding after a few days or months but entailing fatal complications in the bladder or kidneys in two cases and fatal infection from an eschar in a third. In three cases the paralysis or ataxia seemed to be permanent (Violet and Fisher Etude sur la rachistovainisation en gynécologie, *Lyon Chir* 4 421 [Nov 1] 1910). Boldt believed the occasional paralysis of one or both extremities to be due to faulty technique (Boldt, H J Spinal Anesthesia in Gynecology, *New York M J* 101 437 [March 6] 1915).

LEAD POISONING OF PAINTER

To the Editor—Is it likely that a painter will develop lead poisoning when he uses the brush for painting? The patient involved is said to have been a painter for a period of eight years. Granted that a painter is suffering from lead poisoning, how long would one be likely to find stipple cells in the blood after the patient ceased to be exposed to lead? Please omit name

M D Kansas

ANSWER—Large numbers of brush painters who apply paint that contains lead have suffered from lead poisoning of some degree, in the course of years spent in the paint trade. House painters rather than industrial brush painters, are more prone to acquire lead poisoning, owing to the requirements for sandpapering old lead coatings prior and preparatory to repainting. Torch work for the burning off of old coats of paint may give rise to some lead fume but this is not an important source of lead poisoning among painters. Naturally brush painters get some paint on their hands in the absence of great care this paint may enter the mouth through contact with the fingers in smoking taking a chew of tobacco and eating. In short, lead poisoning among brush painters using lead paint is by no means extraordinary.

The detection of stipple cells as a qualitative procedure is of questionable value in the diagnosis of lead poisoning. A few such cells may be found in many persons unexposed to lead after careful search. However, quantitative counts are of some value when the number of such stipple cells is in excess of some such figure as 3,000 per million total red cells. When lead is being absorbed the number of stipple cells may be increased even though no clinical lead poisoning may be established at present. Conversely stipple cells may be found in the blood long after disappearance of clinical manifestations of

lead poisoning. Irregularly increased numbers of stipple cells may be found in the blood examinations as much as a year after exposure or after the cessation of clinical manifestation, but no hard and fast statement can be made in this respect. Further, disabling sequelae of lead poisoning may persist in the absence of any increased numbers of stipple cells.

CHRONIC GONORRHEA

To the Editor—A man aged 22 had acute gonorrheal urethritis in February 1935. He treated himself with acriflavine and continued ordinary activities until March when he had epididymitis on the left side and two weeks later epididymitis on the right side. These inflammations subsided. In July there was still a slight discharge with a positive complement fixation test and a negative Wassermann reaction. A series of Corbus Ferry vaccine injections was given for eight weeks. The discharge stopped after the third injection. At the end of treatment the complement fixation test was still positive but the patient was given a rest. At the end of November the discharge reappeared although the patient had had no further intercourse. Acriflavine prostatic massage and two weeks later again Corbus Ferry vaccine were administered. After four treatments the discharge stopped and a smear was negative even after a prostatic massage. The complement fixation test taken one week ago was still positive. 1 How reliable is the complement fixation test? 2 When will it be safe for the patient to have intercourse? 3 What further treatment would you suggest? Please omit name

M D New York.

ANSWER.—1 A positive gonococcus complement fixation reaction indicates the presence of a focus of living gonococci in the patient. A negative reaction does not exclude gonorrhea.

2 Intercourse will be safe when, following careful study of the prostatic secretion and urethral discharge following provocative injections, one fails to demonstrate gonococci and the complement fixation test is negative.

3 In all probability this patient's infection is lurking in the prostate and vesicles. Continued massage of these glands followed by instillation of a mild solution of silver nitrate (from 0.25 to 0.5 per cent) should help to clear up the infection.

INTERSTITIAL KERATITIS

To the Editor—What would be the proper course of treatment for an eight year old girl with an interstitial keratitis of the right eye of three days duration a positive Wassermann reaction and otherwise good health? Please omit name.

M D, California.

ANSWER—The treatment must be both local and systemic in order to minimize possible damage to the eye. Locally, atropine should be used in sufficient amount to obtain and maintain full pupillary dilatation. Heat in the form of hot wet fomentations should be applied from twenty to thirty minutes at least three times a day and this may be supplemented by short wave diathermy. Antisyphilitic measures applied locally have proved to be entirely without value. Ethylmorphine hydrochloride is of value only in the later stages. As soon as the left eye shows the faintest signs of irritation, as it undoubtedly will, for the majority of cases of interstitial keratitis become bilateral, the pupil should be dilated as widely as possible with atropine.

The systemic treatment must be aimed at the underlying cause of the interstitial keratitis, namely, congenital syphilis. This had best be carried out by a pediatrician or syphilologist rather than an ophthalmologist. In general, these conditions respond better to the use of the arsenical or bismuth preparations than to the time tried mercury injections. But there is no specific effect to be expected and time is an important element.

SENSITIVITY TO INSULIN

To the Editor—I have a patient who is sensitive to all the brands of insulin listed in New and Nonofficial Remedies. Local areas of swelling and induration develop about the site of each injection. Is there any product on the market to be used in such cases and where can it be obtained?

MORRIS FINK M D New York.

ANSWER.—The question of sensitivity to insulin is given full consideration in an article by F N Allan and L R Scherer Insulin Allergy (*Endocrinology* 16 417 [July Aug.] 1932). Several of the commercial houses which manufacture insulin have supplies of crystalline insulin on hand which they will supply for special cases showing sensitiveness to the ordinary commercial forms of insulin.

In many cases desensitization is spontaneous if injections are continued at regular intervals. An interesting point made by Allan and Scherer with regard to desensitization toward insulin is that the change may be localized to the area where the injections are customarily made. A patient who had become free from local reactions complained that the trouble recurred when he entered the hospital at a second visit. It was found that the reaction occurred on the arms where the injections

were given by the nurses, but not on the thighs, where he had been accustomed to give the injections himself. A similar observation was reported by Campbell, Gardiner and Scott, quoted by Allan and Scherer. Efforts to bring about desensitization deliberately have not been very effective although certain cases have been benefited by this means.

SIGNS OF ALCOHOLIC INTOXICATION SEEN AT NECROPSY

To the Editor—Would you be kind enough to answer the following three questions? In the performance of an autopsy is it possible for the physician to state that the deceased was intoxicated at the time of death? What is the greatest length of time after death that the statement of intoxication can be made without any question of doubt? What are the positive tests that can be made on the pathologic examination? Any other facts will also be greatly appreciated. If printed please omit name.

M D Pennsylvania

ANSWER—It is not possible to determine by unaided necropsy whether or not a person was intoxicated by alcohol at the time of death. Redness of the lining of the esophagus and stomach, minute hemorrhages in the gastric mucous membrane, hyperemia and edema of the brain and its membranes, and a more or less definite odor of alcohol from the gastric contents and the organs, especially the brain, though accepted as indications of ingestion of alcohol shortly before death, convey no trustworthy information about the actual amount of alcohol in the body. That can be determined only by chemical examination of the blood supplemented by examination of the contents of the stomach. Other forms of intoxication as well as certain acute infections may cause changes in the organs more or less like those caused by alcohol. At least in many cases there will be grave doubt whether the odor is surely that of alcohol. And finally comes the fact that according to reports acute fatal alcoholic intoxication may occur without causing any recognizable changes in the organs mentioned.

POSSIBLE ARSENICAL POISONING

To the Editor—A patient with severe secondary anemia of cause as yet unknown has for the past six weeks taken as part of his treatment four Blaud Modified Pills three times a day (20 grains or 1.3 Gm. of iron and one-tenth grain or 0.0065 Gm. of arsenic trioxide three times a day). The blood picture shows slight improvement. There are no symptoms of poisoning but can this dosage of arsenic trioxide be continued? Has any harm been done to date? Please omit name.

M D Massachusetts

ANSWER—No harm may have been done, for chronic arsenic poisoning usually produces gastro-intestinal disturbance, irritation of the respiratory tract, skin diseases or neuritis before it results in cachexia. This case nevertheless, illustrates the necessity of omitting the other ingredients, such as arsenic or strychnine from the traditional "tonic" pills when giving large doses of iron in the modern treatment of anemia.

REMOVAL OF TEETH IN PATIENT WITH HEMOPHILIA

To the Editor—A man aged 58 subject to hemophilia has a mouth full of decayed teeth, which should be removed. Can you advise a safe procedure, as on two former occasions he nearly bled to death from the extraction of one tooth? Please omit name.

M D Ohio

ANSWER—The removal of teeth in a person with pronounced hemophilia should be undertaken with the greatest possible care and only after the patient has been under treatment to lower the coagulation time to an irreducible minimum. In the event that teeth must be removed, only one or two should be taken out at a time, and the gums should be carefully sutured by means of a very fine needle. It is usually possible to suture the gums to prevent undue bleeding even in a hemophilic patient if care is exercised in closely approximating the gum surfaces and tying the sutures tight enough to cause definite pressure.

CORNEAL OPACITIES

To the Editor—Please tell me the efficacy of a solution of quinine bisulfate in clearing up old corneal opacities. If of value please state strength of solution used and frequency of applications. Should this query appear in THE JOURNAL, please omit name.

M D Pennsylvania

ANSWER—Dr. Elias Selinger has recommended the use of quinine bisulfate in the treatment of corneal opacities as well as in trachoma. Other ophthalmologists have not noticed any better results from it than from ethylmorphine hydrochloride. It is used in a 2 per cent aqueous solution instilled into the conjunctival sac four times a day or as a 2 per cent ointment in petrolatum three times a day, the patient being instructed to massage for two minutes after the use of the ointment.

Council on Medical Education and Hospitals

THE AMERICAN BOARD OF INTERNAL MEDICINE (INC)

The American Board of Internal Medicine, incorporated Feb. 28, 1936, completed its organization June 15. The officers chosen were Walter L. Bierring, M.D., Des Moines, chairman; Jonathan C. Meakins, M.D., Montreal, vice chairman, and O. H. Perry Pepper, M.D., Philadelphia, secretary-treasurer. These officers with the following six members constitute the present membership of the board: David P. Barr, M.D., St. Louis; Reginald Fitz, M.D., Boston; Ernest E. Irons, M.D., Chicago; William S. Middleton, M.D., Madison, Wis.; John H. Musser, M.D., New Orleans; and G. Gill Richards, M.D., Salt Lake City.

The term of office of each member is to be three years, and no member shall serve more than two consecutive three year terms.

The organization of the board is the result of effective effort on the part of the American College of Physicians in conjunction with the Section on Practice of Medicine of the American Medical Association, and these two organizations are represented in the membership of the board on a five to four ratio respectively.

The American Board of Internal Medicine had previously received the official approval of the two bodies fostering its organization, as well as that of the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

The purpose of the board is to be the certification of specialists in the field of internal medicine and the establishment of qualifications with the required examination procedure for such certification.

While the board is at present chiefly concerned with the qualifications and procedures for certification in the general field of internal medicine, it is intended to inaugurate immediately after July 1, 1937, similar qualifications and procedure for additional certification in certain of the more restricted and specialized branches of internal medicine, as gastroenterology, cardiology, metabolic diseases, tuberculosis and allergic diseases, such special certification to be considered only for candidates who have passed at least the written examination required for certification in general internal medicine. The operation of such a plan would require the active participation and cooperation of recognized representatives from each of such special fields of medicine.

Each applicant for admission to the examination in internal medicine will be required to meet the following standards:

General Qualifications—1. Satisfactory moral and ethical standing in the profession.

2. Membership in the American Medical Association or by courtesy membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided membership in other societies should not be required.

Professional Standing—1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.

2. Completion of an internship of not less than one year in a hospital approved by the same council.

3. In the case of an applicant whose training has been received outside the United States and Canada his credentials must be satisfactory to the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

Special Training—1. Five years must elapse after completion of a year's internship in a hospital approved for intern training by the Council on Medical Education and Hospitals of the American Medical Association before the candidate is eligible for an examination.

2. Three years of this period must be devoted to special training in internal medicine. This requirement should include a period of at least several months of graduate work under proper supervision in anatomy, physiology, biochemistry, pathology, bacteriology or pharmacology particularly as related to the practice of internal medicine.

This work may be carried on in any domestic or foreign medical school or laboratory recognized by the Council on Medical Education and Hospitals of the American Medical Association as offering appropriate facilities for this type of postgraduate experience or it may include a period of at least several months of graduate work under proper supervision in internal medicine or in its restricted and specialized branches in any domestic or foreign hospital, clinic or dispensary or under the

immediate preceptorship of an internist recognized by the Council on Medical Education and Hospitals of the American Medical Association as offering appropriate facilities for this type of postgraduate experience.

3 An education period of not less than two years of special study nor practice in the field of internal medicine or in its more restricted and specialized branches.

The American Board of Internal Medicine does not propose to establish fixed rules for the preliminary training of candidates for certification in this field. Broad general principles for training, however, may be outlined although such suggestions as are made must of necessity be subject to constant changes reflecting the dynamic nature of the specialty.

A sound knowledge of physiology, biochemistry, pharmacology, anatomy, bacteriology and pathology so far as they apply to disease is regarded as essential for continued progress of the individual who practices internal medicine. The mere factual knowledge of medicine and its basic sciences is not sufficient. The candidate must have had training in their use in furthering his understanding in clinical medicine. This implies practical experience under the guidance of older men who bring to their clinical problems ripe knowledge and critical judgment. Preparation to meet this requirement adequately may be even more difficult to obtain than the so-called scientific training. It may however be acquired in the following ways:

(a) By work in a well organized hospital outdoor clinic conducted by competent physicians.

(b) By a prolonged period of resident hospital appointments likewise directed by skilled physicians.

(c) By a period of training in intimate association with a well trained and critical physician who takes the trouble to teach and guide his assistants rather than to expect him only to carry out the minor drudgery of a busy practice.

4 The board does not consider it to the best interests of internal medicine in this country that rigid rules as to where or how the training outlined shall be obtained. Medical teaching and knowledge are international. The opportunities of prospective candidates are not all the same. Some may have the opportunity of widening their knowledge by a period of study abroad. Others at the other extreme may be restricted to a comparatively narrow geographic area and their more detailed training must be obtained in short periods scattered over a longer time. Although it is laid down that at least five years must elapse between the termination of the first intern year and when the candidate is eligible to take the examination a longer period is advisable. The board wishes to emphasize that the time and training are but means to the end of acquiring a broadness and depth of knowledge of internal medicine which the candidate must demonstrate to the board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge as best he may, rests with the candidate while the responsibility of maintaining the standard of knowledge required for certification devolves on the board.

Method of Examination—The examination required of candidates for certification as specialists in internal medicine will comprise part I (written) and part II (practical or clinical).

PART I—The written examination is to be held simultaneously in different sections of the United States and Canada and will include:

(a) Questions in applied physiology, physiologic chemistry, pathology, pharmacology and the cultural aspects of medicine.

(b) Questions in general internal medicine.

The first written examination will be held in December 1936 and candidates successful in this written test will be eligible for the first practical or clinical examination, which will be conducted by members of the board near the time of the annual session of the American College of Physicians at St. Louis in April 1937.

The fee for examination is \$40, which must accompany the application and an additional fee of \$10 is required when the certificate is issued.

Application blanks and further information can be obtained by addressing the office of the chairman, Walter L. Bjerring, M.D., 406 Sixth Avenue, Des Moines, Iowa.

Book Notices

A Manual of the Common Contagious Diseases By Philip Moen Stimson A.B. M.D. Assistant Professor of Clinical Pediatrics Cornell University Medical College Second edition Fabrikoid Price \$4 Pp 439 with 56 illustrations Philadelphia Lea & Febiger 1936

This invaluable and compact manual has been thoroughly revised and brought down to date. A new chapter on smallpox has been added and chapters dealing with poliomyelitis, whooping cough, measles and meningitis have been changed to meet recent therapeutic advances. This has been accomplished without any undue expansion, and the comprehensive conciseness that characterized the first edition has been maintained. It is doubtful whether any book in any language presents the current information on the acute contagious diseases in such a lucid and compact manner as does this manual. It is well balanced, direct in its manner of presentation, and authoritative. The book is earnestly recommended to the practicing physician and to the student of medicine as an invaluable and necessary part of his library.

Children's Fears By Arthur T. Jersild and Frances B. Holmes Child Development Monographs Monograph No. 20 Paper Price \$2.75 Pp 356 with illustrations New York Bureau of Publications Teachers College Columbia University 1935

This monograph represents a series of studies covering a period of three years at the Child Development Institute of Teachers College, Columbia University. The material deals with the various types of fears that are most prevalent at all ages and an analysis of the data for indications of developmental trends and causal factors. The methods used to elaborate this material were many including direct observation of children by parents and adults, interviews with parents and teachers, case studies and experimental situations. The monograph is divided into four parts: (1) children's fears observed in daily life by parents and other adults; (2) fears reported by children themselves and fears recalled from childhood by adults; (3) an experimental study of the fears of young children; (4) the nature and prevention of childhood fears. The monograph is valuable for any one interested in the emotional behavior of children. The authors have shown unusual skill in planning and evaluating their investigation. The work is highly recommended to the profession.

Invisible Radiations of Organisms By Otto Bahn Professor of Bacteriology Cornell University With an Introduction to the Physics of Radiation By Sidney W. Barnes Research Associate in Physics University of Rochester Band IV Protoplasma Monographien Herausgegeben von R. Chambers et al. Cloth Price 13.20 marks Pp 215 with 32 illustrations Berlin Verlag von Gebrüder Borntraeger 1936

This is a critical discussion of the accumulated evidence with regard to the question as to whether or not there is a mitogenic radiation. The author who has studied the problem extensively himself, believes that the evidence for its existence is much more convincing than the negative observations which can usually be explained as resulting from the use of detectors that are not in a suitable state. The history of the subject in brief is that in 1923 Gurwitsch found that if he exposed one side of the zone of meristematic growth of an onion root to another growing root the exposed side when sectioned after a time showed more dividing nuclei than the other. The effect could be obtained through quartz but not through glass, indicating that it was due to ultraviolet rays of wavelength shorter than 3000 angstroms and it was concluded therefore both that the growing root emitted radiation of this kind and that the absorption of this by another growing root induced cell division within it. This effect on mitosis gave rise to the name mitogenic radiation. Subsequent work has established that the range is from 1900 to 2500 angstroms and that not only will monochromatic light of these wavelengths from physical sources produce the mitogenic effect but radiation capable of producing the effect is given off by a large number of living tissues growing tissue in general being a more active emitter than adult. The acceptance of these results has been delayed for two principal reasons: first the radiation emitted is so weak that its detection by photography or other physical means is inconclusive and second it did not seem likely that there could be any mechanism within the living cell or body fluids capable of pro-

ducing light of such high energy. The first difficulty has been largely overcome by the use of better biologic methods of detection, the best developed of which is based on the influence of the radiation on the budding of yeast, which gives sufficiently consistent results to be quite convincing. The second difficulty has been removed by the finding that many chemical reactions in solution give off a similar very weak ultraviolet radiation. Examples of these reactions that have been shown to account for some of the mitogenic radiation are oxidation, glycolysis, creatinine hydrolysis and proteolysis. The radiation from blood for example has been shown to be due to a number of such reactions. Of special medical interest is the fact that malignant tumors radiate strongly in comparison to the tissues of growing animals which radiate weakly. On the other hand, the blood of patients with malignant tissue ceases to radiate while normal blood radiates quite well. The blood continues to radiate during most diseases, but there are exceptions, such as leukemia and severe septicemia. It is indicated that the healing of wounds is accelerated by irradiation at the proper time. The effect from menstruating women, allegedly harmful to yeast cultures in industry may be due to a radiation from oxycholesterol which may account also for observations that bacteria on seeded plates are killed by handling by some persons. An introductory section on the physics of radiation by Barnes makes the book complete in itself, so that it can be understood readily by the general reader.

Elements of Psychology By Knight Dunlap Professor of Psychology in the University of California at Los Angeles. Cloth Price \$3 Pp 489 with 65 illustrations St. Louis C. V. Mosby Company 1936

Knight Dunlap is well known in the field of psychology. While he differs from some of the other writers in this field in rejecting the concept of image (but not imagination) and also in the rejection of instinct, the present book, as a whole, will not be found to be a great departure from other elementary textbooks on this subject. It is subject to the usual criticism that it is more of a work on the physiology of the nervous system than one in psychology and that its discussions of reflex and of body mechanisms involved in thought and psychologic response really stress the physiologic nevertheless it is improbable that a knowledge of these structures will hurt the beginning psychologist. The point of view is highly academic. Since the amount of material in the book is not great and covers perception of space and time, emotions, thinking, learning, psychologic measurements and individual differences as well as the problems of maladjustment and readjustment, the space devoted to specific problems cannot be extensive. Its probable value when compared with similar works lies in the soundness of the author's selection of material rather than in anything novel. The material given on mental tests and other practical considerations is more scanty than one would hope for in a book published in 1936 and there is much stress laid on psychophysical apparatus and experimental material which might be better left to a special course in experimental psychology rather than to the elementary student. There is a satisfactory glossary. The references at the end of each chapter are insufficient.

Manuel de pathologie médicale Par Maurice Journé et Pierre Noël Deschamps Third edition Cloth Price 110 francs Pp 1702 Paris Masson & Cie 1935

The authors cannot be accused of verbosity as far as preface is concerned, as there is no preface at all. A review of the book allows the conclusion that the work has been written for students for whom it will be a source of enjoyment and stimulation. A short discussion of etiology, symptomatology, clinical course, diagnosis, prognosis and treatment follows the description of the pathology in each chapter. Numerous remarks as to the clinical and therapeutic features are skilfully woven into the presentation of the pathologic aspect of the disease under discussion. The space allotted each subject is in proportion to its clinical importance. The first chapter is devoted to diseases of infectious and parasitic origin. The remaining chapters treat the entire series of diseases according to their regional distribution. Several statements attract special attention. Intratracheal injections of antipneumococcus or antistreptococcus serum are advocated in the pneumonic type of influenza. An intranasal spray of diacetylmorphine is recom-

mended for the treatment of bronchial asthma. Fractional examination of gastric contents, the Dick test and phonocardiographic method of recording heart sounds are not mentioned. General anesthesia is considered as contraindicated in thyroidectomies. In accordance with the scope of the book, bibliographic references have been omitted. All the information is down to date, the style simple and pleasing, the format handy.

La périodicité saisonnière des maladies épidémiques et en particulier de la poliomyélite. Par G. Hornus, Assistant à l'Institut Pasteur. Préface de C. Lévy. Monographies de l'Institut Pasteur. Paper. Price 28 francs. Pp 137 with 23 illustrations. Paris: Masson & Cie 1935.

Hornus in his monograph on seasonal periodicity in epidemic diseases, particularly poliomyelitis, has shown that these diseases are more prevalent in the temperate zones than in the Mediterranean basin. But little is known of the epidemiology of infectious diseases in the tropical regions. The more one approaches the equator from north to south the less marked is the frequency of infectious diseases, the more so for poliomyelitis. In the temperate zone south and north of the equator there is a six months difference in seasonal periods. There are several charts in this monograph illustrating the frequency of poliomyelitis in different months of the year, and the results show that there are two peaks when poliomyelitis is at its height, one is during the summer and fall, and the other during the spring. The author discusses several possible factors that have to do with seasonal distribution of poliomyelitis. In the monograph meteorological factors, such as temperature, which in itself is not as important as the barometric pressure, are discussed. Humidity, the author believes, makes the mucosa of the nasal pharynx more permeable to the droplets of poliomyelitis virus, provided it is proved that the infection spreads by way of the respiratory tract. Also discussed are atmospheric pressure, wind, insulation, atmospheric electricity and cosmic and terrestrial factors, the latter not being quite clearly described. The virulence and variability of the pathogenic organism that causes poliomyelitis are mentioned.

Bodyscope. By Ralph H. Segal. Over 80 full length and detailed anatomical illustrations and 20,000 words of reference text. Boards. Price \$3.50. Brooklyn, New York: J. Sklar Mfg. Co. 1935.

This is a highly ingenious device for making readily available to the average man a knowledge of human anatomy. It includes an outline of the anatomy of the tissue of the body classified by systems with various special sections of the body illustrated on charts shown on revolving wheels. The second and third pages reveal figures of a man and a woman, with various layers of the viscera, illustrated on the revolving wheels so as to show the contents of the abdomen at various levels. As the wheels revolve, the text concerning the organs also revolves so as to be available with the picture. The last page shows heart, lungs and sagittal sections. There are inserts showing the portraits of famous contributors to medicine and also some facts regarding their lives. As a ready reference to human anatomy and physiology, this device should be exceedingly useful. If there is any criticism to make it concerns the great size of the book which measures 16 by 19 inches and therefore is inconvenient except on a large table.

Die Herzkrankheiten im Röntgenbild und Elektrokardiogramm. Von Dr. med. Paul Uhlenhuth, a. o. Prof. an der Universität Bonn/Rhein. Paper. Price 36 marks. Pp 318 with 316 illustrations. Leipzig: Johann Ambrosius Barth 1936.

The author has attempted to present in a systematic fashion the clinical details of heart disease together with the changes to be seen in x-ray plates and in electrocardiograms. The purpose of this correlation is to give the clinician an opportunity to see how these graphic methods help in handling diseases of the heart. The many roentgenograms and electrocardiograms are placed at the end of every chapter each with a legend beneath and a brief synopsis of the clinical story on the opposite page. The reader thus has the opportunity of studying the text, the roentgenograms and electrocardiograms separately should he so desire. The material is timely, the presentation is simple, the printing excellent and the illustrations well reproduced. There are a number of useful diagnostic tables and compilations of differential diagnosis. There are some excellent chapters on the measurements used in inter-

preting the x-ray plates, and one dealing with roentgenography is included. A chapter is devoted to the theory of the electrocardiogram. The rest of the book covers the various clinical conditions to be encountered and is thorough in its scope. The author may be accused of presenting too much controversial material still held *sub judice*, but this is a minor criticism. The book can be unequivocally recommended to the physician interested in heart disease. It will show him the field of usefulness of these two graphic methods of studying the heart. The expert will find it useful in obtaining the present point of view of the German school.

A Synopsis of Physiology. By A. Rendle Short, B.Sc. M.D., F.R.C.S. Professor of Surgery, University of Bristol, and C. I. Ham, M.B. B.Sc., F.R.C.S. Second edition. Edited by C. L. G. Pratt, M.Sc., M.D., Lecturer in Physiology, St. Thomas's Hospital Medical School. Cloth. Price \$3.50. Pp 312 with 26 illustrations. Baltimore: William Wood & Company 1936.

This compendium of physiology has been recedited. The fact that the senior author is professor of surgery in a British university will assure the reader that the emphasis is clinical rather than academic. The concise form of the work leads to undesirable dogmatism and to many statements that are not rigorously true. Properly and critically used, this kind of a book might be valuable, particularly in reviewing for examinations. Unfortunately, works of this kind are ordinarily employed by persons without a basis for critical judgment. It is consequently to be recommended cautiously. If the material were a little more extensive, the book might serve as an elementary reference dictionary. Much new material has been added in the second edition, including such highly technical data as the tentative structural formulas for ergosterol, vitamin A and the female sex hormones. The inclusion of such material gives a fallacious impression of scholarly completeness.

Treatment in General Practice. The Management of Some Major Medical Disorders. 1. Articles Republished from the British Medical Journal. Cloth. Price 8s. 6d. Pp 250 with 6 illustrations. London: H. K. Lewis & Co. Ltd. 1936.

This collection of articles, which were published weekly in the *British Medical Journal* chiefly during the first half of 1935, is a welcome presentation of the practice of eminent British teachers of clinical medicine. The present volume deals chiefly with diseases of the respiratory and circulatory system and some of the acute specific fevers. The series planned, which this is the first volume, is intended to present a panorama of current therapeutics. As such it should be of help to the teacher as well as to the student but most of all to the general practitioner.

Seuchenerkrankung und Klimaforschung. Die Ergebnisse der Klimaforschung in ihrer Bedeutung für die Epidemiologie. Von Dr. med. Friedrich Wolter, Leiter des Hamburgischen Forschungsinstituts für Epidemiologie. Nach einem Vortrag auf der bloklimatischen Tagung anlässlich des 25jährigen Jubiläums der Deutschen Meteorologischen Gesellschaft in Hamburg. Kleine Hippokrates Bücher! Band V. Herausgegeben von Prof. Dr. med. Kurt Klare, Scheldt. Boards. Price 3 marks. Pp 43. Stuttgart & Leipzig: Hippokrates Verlag GMBH 1935.

In this small monograph Wolter presents a readable account of epidemiology regarded not from the narrow range of the bacteriologist but from the broader point of view of the hygienist who considers the phenomena involved in the development and the recession of epidemics from many other angles. In this particular treatise he discusses the relation of epidemics to climatic cycles in particular to the Bruckner cycle (thirty-five years). There seems little doubt that climatic cycles occur—although they are by no means absolute in their rhythm—so, too, that cycles of long range appear to overlap, and that meteorologists can determine eleven, seventeen and thirty-five year cycles, as well as longer periods of increasing or decreasing solar activity or of relative wetness or dryness. It is logical that the organic world must adjust itself to such cosmic and terrestrial alterations in environment, with resulting difference in the chemical and endocrine and other physiological mechanisms. So far the only observations extending over a period of several years are those of Petersen. That pathological expression of such changes will be found might seem obvious but it will require long time chemical observation of human beings before the possible integrations can be evaluated and at the present time there is neither understanding nor consequent financial support for studies of this type. This is the handi-

that underlies all monographs of the type here reviewed. The observations are interesting and suggestive but cannot at the present time go beyond this point.

Evans' Recent Advances in Physiology. Fifth edition revised by W. H. Newton, M.D., M.Sc., Senior Lecturer in Physiology, University College London. Cloth Price \$5. Pp. 500 with 120 illustrations. Philadelphia: P. Blakiston & Son & Co., Inc. 1936.

This is a stimulating synthetic review of some aspects of recent physiologic literature. Largely rewritten by Newton, it retains the clarity and pertinence achieved by Lovatt Evans. The topics discussed refer to the circulation, respiration, nervous processes, urine secretion and sex hormones. In addition, the little discussed physiologic mechanisms involved in micturition and defecation have been given a thorough treatment. Evans himself has contributed the chapter on the metabolism of cardiac muscle, a field in which he has made numerous discoveries. A clear presentation is given of the importance of the diastolic ventricular volume in determining energy liberation in contraction. It is almost superfluous to mention the specific subjects that are treated in an especially clear way, because it would include most of the topics discussed. The book is decidedly worth while as a means of keeping abreast of the major developments in physiology.

The Integration of the Endocrine System. Being the Fifth Horsley Memorial Lecture Delivered at University College Hospital Medical School. By Sir Walter Langdon Brown, M.D., F.R.C.P. Paper Price 7s. 6d. Pp. 54. New York: Macmillan Company, Cambridge: University Press, 1935.

This is the fifth Horsley Memorial Lecture published in a pocket size edition and represents a scholarly and provocative discussion of the interrelationships of the endocrine system. Beginning with a short historical development of the early researches on the endocrine glands, the author stresses three recent lines of advance which are leading to a clearer conception of the integration of the endocrine system: (1) the diencephalon, (2) the pituitary and (3) the hormones of the pituitary gland. Each is briefly discussed and finally the author proposes the view that, while the endocrine glands are autonomous in their activity, they can be modified and controlled by diencephalic centers which operate directly through the sympathetic nervous system or indirectly through the chemical activities of the anterior pituitary.

Die tierischen Parasiten der Haus- und Nutztiere sowie des Menschen. Ein Lehr- und Handbuch mit Bestimmungstabellen für Tierärzte, Ärzte und Studierende. Von Dr. med. Josef Flebinger, Diplomierter Tierarzt o. b. Professor an der Tierärztlichen Hochschule und Privatdozent der medizinischen Fakultät der Universität in Wien. Third edition. Paper Price 17.50 marks. Pp. 375 with 353 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1936.

The present account of the animal parasites is divided into two parts. The first, which covers only thirty-eight pages, gives a general discussion of parasitism, invasion, transmission and physiology of parasites, effects of parasites on the host, immune reactions and technical methods. The second section, which is extensive and comprises 302 pages, gives a systematic description of most of the protozoa, worms and arthropods of interest to medical and veterinary sciences. The descriptions of individual forms are necessarily short but in general accurate. The author has appended to his systematic account a parasite catalogue giving the systematic position of the various parasites and indicating their hosts. He has also included a host catalogue showing the parasites under each host. The chief criticism that can be raised against the text is the almost complete lack of references to French, English and American authors.

Medical Papers Dedicated to Henry Asbury Christian, Physician and Teacher in Honor of His Sixtieth Birthday, February 17, 1936. From His Present and Past Associates and House Officers at the Peter Bent Brigham Hospital, Boston, Mass. Cloth Price \$10. Pp. 1000 with illustrations. Baltimore: Waverly Press, Inc. 1936.

This volume is a collection of medical papers dedicated to Dr. Henry A. Christian in honor of his sixtieth birthday. The contributions are from his present and past associates and house officers of the Peter Bent Brigham Hospital. The book is a fitting tribute and token of appreciation that reflects the inspiration and guidance of a great clinician and teacher. The

papers are all of current medical interest covering a wide field and represent, for the most part, original investigations. They are a testimonial to an inspiring and critical preceptor. While Dr. Christian's personal contributions have been chiefly in the domain of cardiovascular-renal diseases, the collected works of his assistants reflect his diversity of medical interest. At the end of the book is a register of former and present members of the Peter Bent Brigham Hospital Medical staff. The volume is attractively bound and printed and deserves a place in every medical library.

Eye, Ear, Nose and Throat Manual for Nurses. By Roy H. Parkinson, M.D., Head Oculist and Aurist to St. Joseph's Hospital, San Francisco. Third edition. Cloth Price \$2.25. Pp. 232 with 72 illustrations. St. Louis: C. V. Mosby Company, 1936.

In this manual there is a certain amount of anatomy which is necessary for nurses to know, and this section is embellished with an adequate number of illustrations. In a brief fashion the common diseases of the eye, ear, nose and throat are discussed, and lastly under the caption of operating room technique, are numerous illustrations identifying the instruments used in the different operations. This sort of textbook is valuable not only for student nurses but even more so for nursing supervisors and others who have to instruct them. The author does not make the mistake of setting forth information with which student nurses need not be concerned.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Discharge in Bankruptcy a Bar to Claim for Malpractice.—The defendant, a practicing physician in Michigan, injured the plaintiff's urethra in an attempt to introduce sounds. The plaintiff sued the physician and obtained a judgment against him, the court finding that the treatment had been done "carelessly, recklessly, wantonly and negligently."

Subsequently the physician moved to Wisconsin and in that state the plaintiff brought suit on the Michigan judgment but before final action in the case the physician was adjudicated a bankrupt by the United States district court for the western district of Wisconsin and was later granted a full discharge from all provable debts. Subsequent to the adjudication in bankruptcy, but prior to the final discharge, the plaintiff obtained a judgment against the defendant, based on the Michigan judgment. Executions against the defendant's property, however, were returned unsatisfied and the plaintiff sought to have the physician imprisoned for nonpayment of the judgment. The trial court refused to order the arrest of the physician, and the plaintiff appealed to the Supreme Court of Wisconsin.

The correctness of the ruling of the trial court, said the Supreme Court, depends on whether or not the plaintiff's claim against the physician was exempt from the operation of the discharge in bankruptcy under section 18 of the bankruptcy act, providing in part as follows:

A discharge in bankruptcy shall release a bankrupt from all of his provable debts except such as are liabilities for willful and malicious injuries to the person or property of another [Italics supplied].

Was the plaintiff's claim one for "willful and malicious" injury? The whole pleading in the malpractice suit, said the Supreme Court, and the judgment of the Michigan court placed the acts of the physician in the field of negligence. There was no intimation that the physician felt any ill will or malice toward the plaintiff. The most extreme statement in the pleading or in the findings of the Michigan court said the Wisconsin court properly viewed is to the effect that the physician was employed to treat the plaintiff with the expectation that he possessed and would use the care and skill required of physicians who undertake treatment of patients and that the physician failed to rise to his obligation, was reckless and unskillful in his treatment of his patient. But said the Supreme Court, in the absence of

wilful and intentional acts and of malice and hatred an injury due to negligence is not caused by wilful and malicious conduct. The use by the Michigan court in describing the treatment rendered by the defendant of the words carelessly, recklessly and wantonly was to describe the negligence of the defendant and did not mean that the defendant wilfully and maliciously injured the plaintiff. In the opinion of the Supreme Court of Wisconsin therefore the plaintiff had a provable claim in the bankruptcy proceeding from which the defendant was released by the discharge in bankruptcy. The judgment of the trial court refusing to order the arrest of the physician was affirmed—*Schacht v. Bonacci* (115) 264 N. W. 625.

Workmen's Compensation Acts Atrophy of Leg Following Trauma to Sciatic Nerve—The claimant Bruno, an employee of the defendant company, in the course of his employment sustained a fracture of one of his great toes. He was awarded compensation for that injury. Later, he applied to the workmen's compensation bureau for further compensation claiming that at the time of the accident he had fallen backward and had injured his back resulting in a permanent atrophy of his left leg. The deputy commissioner denied him further compensation because in his opinion, the medical testimony showed the atrophy had existed prior to the accident and had not been aggravated by the trauma. On appeal the court of common pleas held that the accident caused the claimant to fall backwards to the floor striking his back and causing him injury to the sciatic nerve which caused an atrophy and foot drop of the left leg and awarded additional compensation. The employer appealed to the supreme court of New Jersey.

According to the medical testimony said the supreme court the atrophy of the claimant's leg might well have followed a traumatic injury. Such testimony tended to exclude other possible causes for the claimant's condition such as syphilis, infantile paralysis or diphtheria. Furthermore the evidence showed that prior to the accident the claimant had been sound, healthy and able to do heavy work. The court concluded from the evidence presented, that the atrophy of the claimant's left leg had resulted from the accident and that therefore the claimant was entitled to further compensation.

The Court of Errors and Appeals affirmed on appeal the judgment granting the claimant additional compensation—*Bruno v. Turner & Co. Inc.* (N. J.) 183 1 173.

Workmen's Compensation Acts Frost-Bite a Compensable Injury—The claimant a policeman sustained frost-bite of his hands while on night patrol duty during the winter. Gangrene set in and some amputation was necessary. From an award of the workmen's compensation bureau granting him compensation the township of Woodbridge his employer appealed to the supreme court of New Jersey.

The weather was unusually cold said the supreme court, and the claimant's employment obliged him to use his hands and prevented him from seeking shelter. He was exposed to a different risk than the public generally because he was on duty from 6 p. m. to 4 a. m. with the exception of a lunch hour. The claimant the court concluded sustained a compensable accidental injury arising out of and in the course of his employment—*Mattler v. Woodbridge Tp.* (N. J.) 183 4 150.

Health Insurance Permanent Disability in Relation to Pulmonary Tuberculosis—Permanent disability "said the United States circuit court of appeals means that which is continuing as opposed to that which is temporary and separate and distinct periods of temporary disability do not constitute that which is permanent. In the present case a veteran permitted his war risk insurance policy to lapse in September 1919. Approximately thirteen years later when admittedly he was totally and permanently disabled from tuberculosis he brought suit on the policy claiming that he had been to all and permanently disabled during the life of the policy. The United States district court gave judgment for the veteran and an appeal was taken to the circuit court of appeals.

There was a dissenting opinion said the court, that the disease from which the veteran was ultimately disabled resulted from tuberculosis during the life of the veteran's policy. There is no reasonable presumption that before the

lapse of the policy it had progressed to the stage where it was totally disabling, or where its persistence might reasonably have been expected to continue permanently. In *United States v. Grew*, 68 F. (2d) 124, it was observed that there are "a great number of maladies which are or may be steadily progressive but which are not wholly incapacitating in their early stages," and that "there are others which, though properly to be considered as total disabilities in the incipient stages, are often arrested to the extent that the patient may thereafter lead an industrious and a useful life. Pulmonary tuberculosis is one of the commonest of the latter class." The present case, said the court, must be aligned with *U. S. v. Sumner*, 69 F. (2d) 770, wherein it was said that, even if tuberculosis was totally disabling in its incipient stages, evidence of this carries no inference that the disability is reasonably certain to continue through life. The fact, continued the court, that the veteran, about two years after the policy had lapsed, filed a claim with the Veterans' Bureau contending that he was 50 per cent disabled, that he refused proffered hospitalization for his tuberculous condition, and that he delayed approximately thirteen years making claim under the policy, all prevent any reasonable inference being drawn that the veteran was permanently and totally disabled during the life of the policy. The judgment of the trial court for the veteran was therefore reversed—*United States v. Middleton* 81 F. (2d) 205.

Workmen's Compensation Acts Compensability of Gonorrheal Ophthalmia—The employee lost the sight of one of his eyes as the result of gonorrheal infection. He filed a claim for compensation under the workmen's compensation act of Texas. The district court granted compensation, after the industrial board had denied the employee's claim, and the company and its insurer appealed to the court of civil appeals of Texas, Beaumont.

The employee contended that he contracted the infection from using a toilet on the premises where he was employed. The verdict of the jury for the employee, said the court of civil appeals, was based on two presumptions: (1) that there were gonococci on the toilet used by the employee at the place of his employment, and (2) that the employee became infected from using this particular toilet. But, the court said, there was no evidence to support either presumption. The jury could not presume an "infected toilet," and then, piling presumption on presumption, presume that the employee was infected by the toilet. The verdict, therefore, was wholly without support, for the jury went into the domain of conjecture and piled one presumption on another. The judgment of the trial court was therefore reversed and the case remanded for a new trial, the appellate court being of the opinion that the case had not been fully developed on the first trial—*Standard Accident Ins. Co. v. Ritchie* (Texas), 80 S. W. (2d) 498.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Alabama Medical Association Journal, Montgomery 5 373-404 (May) 1936

Uterine Contraction Rings. Report of Eight Cases. T. M. Boulware. Birmingham—p. 373.

Ulcers of the Leg. J. E. Cameron. Alexander City—p. 377.

*Blood Platelet Numbers in Normal Men and Women. J. L. Brakefield and Kate Malone. Birmingham—p. 380.

Alabama's Eighty Nine Years of Medical Organization. Brief History of the Association. D. L. Cannon. Montgomery—p. 385.

Blood Platelet Numbers in Normal Persons—Brakefield and Malone determined the blood platelet numbers in ten men and five women living the normal routine of college life. The counts were made at a definite hour from week to week in the men over a period of ten weeks and in the women over a period of five weeks. An analysis of the work on the men shows that only 4 per cent of the counts were in excess of 500,000 per cubic millimeter. Approximately 20 per cent were slightly in excess to 400,000 per cubic millimeter, while 68 per cent fell between 300,000 and 400,000. The average for all the determinations was 373,000. There were no greater variations in the counts made from week to week than were found at different periods within one day. A range of from 350,000 to 400,000 per cubic millimeter may be considered normal for the group of men studied. In the women the determinations ran consistently lower. None exceeded 400,000 per cubic millimeter, while approximately 90 per cent fell between 300,000 and 330,000 per cubic millimeter. The average for the group was 328,000 per cubic millimeter from week to week. The variations within one day paralleled closely those from week to week and the average for the group was 335,000 per cubic millimeter.

American Heart Journal, St. Louis

Intermittent Claudication Studied by a Graphic Method. L. H. Hitzrot. M. Naide and E. M. Landis. Philadelphia—p. 513.

Ineffectiveness of Drugs on Collateral Flow After Experimental Coronary Occlusion in Dogs. C. J. Wiggers and H. D. Green. Cleveland—p. 527.

Paradox of Chiari's Network. Review and Report of Case of Chiari's Network Ensnaring Large Embolus. W. M. Yater. Washington D. C.—p. 542.

Auriculoventricular Dissociation and Adams-Stokes Syndrome in Acute Coronary Vessel Closure. S. P. Schwartz. New York—p. 554.

Coarctation of Aorta (Adult Type). Clinical and Experimental Studies. J. Flexner. New York—p. 572.

*Nonfilament Leukocyte Count After Coronary Artery Occlusion. D. E. Goodrich and F. J. Smith. Detroit—p. 581.

Analysis of Relations of Coronary Constrictor and Dilator Nerves in Cervical Vagus-sympathetic of Dog. C. W. Greene. Columbia Mo.—p. 592.

Temperature of Flare as an Index of Intensity of Histamine Skin Reaction. S. Perlow. Chicago—p. 605.

Alternation Phenomena in Electrocardiogram. Occurrence in Patient with Active Carotid Sinus Reflex. M. E. Missal and R. B. Cram. Rochester N. Y.—p. 611.

Syncope Attacks Due to Congenital Anomaly of Right Common Carotid Artery. H. L. Smith and H. C. Hinshaw. Rochester Minn.—p. 619.

Complete Heart Block in Hyperthyroidism. Report of Case. L. G. Stever. Cleveland—p. 623.

Acquired Interventricular Septal Defect Associated with Long Standing Congestive Heart Failure. Case. H. Gross and S. P. Schwartz. New York—p. 626.

Nonfilament Leukocyte Count After Coronary Occlusion—In applying the filament-nonfilament count in several patients after coronary occlusion Goodrich and Smith were struck with the fact that there was a left shift which was frequently pronounced. It was then decided to follow several such consecutive cases doing frequent simultaneous total leukocyte counts and differential counts according to the usual type as well as filament nonfilament counts plotting the results

graphically. This procedure was carried out in fifteen cases of coronary artery occlusion, and a total of 189 such counts were made. They found that the total white cell count is increased after coronary artery occlusion, averaging from 13,000 to 18,000 in the first four days. In a fatal case one count as high as 35,700 was encountered. The average leukocyte count has been found to be slightly higher in the patients who died than in those who recovered. The polymorphonuclear neutrophil percentage is above normal, being somewhat higher in the fatal group than in the recovered group. The average non-filament curve was found to be almost twice as high in the fatal cases of coronary occlusion as in the recovering group, and in the combined graph of fatal cases the nonfilament average was as high as the filamented average on the seventh and eleventh days, while in the recovering group, although a few cases showed an intersection of these two curves on the fourth day, in the main there was a wide separation between them. The eosinophils were absent in the four fatal cases up to the fifth day the curve slowly rising to 16 per cent on the tenth day and then falling to zero on the twelfth day. The recovering group showed an earlier appearance of eosinophils and a higher and more progressive rise to 36 per cent on the fifteenth day. The daily plotting of graphs of the differential and filament nonfilament counts after acute coronary occlusion gives information of distinct value in estimating the prognosis, and this information is superior to that obtainable from the total leukocyte count alone.

Melanomas. D. H. Affleck. Baltimore—p. 120.

Ewing Sarcoma in Ribs—Bergstrand describes four cases of Ewing sarcoma in the ribs, all similar. The tumors originated from the posterior portion of one of the ribs and grew like sponges into the pleural cavity pushing the lifted pericostum and the pleura before them. The greatest length of the tumors was along the rib. The surface was coarsely lobate

The ribs presented a characteristic increase in density and volume and spicules were formed. The latter occurred only on the inside of the rib, however, where the periosteum was elevated but not on the outside even though the tumor tissue grew around the rib. The loosening of the periosteum began at the point of attachment of the intercostal muscles. One patient, treated by extirpation and x-rays is alive and well five and a half years after the operation although metastases had occurred in the lungs two years after the operation. These disappeared under roentgen treatment. The author believes that practically all Ewing sarcomas are localized to those parts of the skeleton in which ossification begins in the second month of fetal life. The first formation of the later ossifying blastema takes place at the same points. As the cells of Ewing sarcoma are similar to these blastema cells the conclusion might be drawn tentatively that Ewing sarcomas are due to a disturbance in the formation of the skeleton at an early stage of fetal life.

Significance of Monocytes in Agranulocytosis—Rosenthal and Abel believe that the differentiation of agranulocytosis from other diseases is best accomplished by means of a blood examination which shows the characteristic profound leukopenia and neutropenia. It is possible to differentiate three main types of agranulocytosis at the onset of symptoms, according to the predominance of certain cells: (1) agranulocytosis with relative lymphocytosis, (2) agranulocytosis with unusual monocytosis (leukopenic infectious monocytosis) and (3) hypoleukocytic angina in which all the symptoms of agranulocytosis are present, including leukopenia, but without much change in the differential blood count. In addition to eight cases previously reported, they discuss fourteen cases of agranulocytosis with monocytosis (leukopenic infectious monocytosis) and show the possible relation of this form of agranulocytosis in certain cases to drugs. Marked monocytosis in certain cases of agranulocytosis has received slight attention. The most striking hematologic feature of agranulocytosis is not only the relative increase in the percentage of monocytes but, in some cases, an actual absolute increase. The monocytes correspond to the large mononuclear and transitional cells first described by Ehrlich. They are larger than the neutrophils and present the characteristic irregular rounded or s-shaped, finely reticulated, nucleus. The cytoplasm usually stains evenly and contains a few discrete azure granules. Oxidase positive granules can be demonstrated in the cytoplasm with the proper stains. Supravital staining by means of neutral red and Janus green B brings out the characteristic features of this type of cell: the evenly distributed and equal sized vacuoles (so-called roset) and a few evenly distributed small mitochondria. They move very slowly when observed in the warm box. In addition to these cells, large clastocytes or macrophages may be found in the blood, obtained from the lobe of the ear at times up to 10 per cent or more. These apparently, are more numerous in the tissues. There is a leukopenia varying from 900 to 4,000 cells associated with a monocytosis at the onset of the disease. In three cases in the present group a leukopenia, neutropenia and monocytosis persisted after the initial attack. The prognosis is more favorable in agranulocytosis accompanied by monocytosis. In the authors' series of twenty-two cases seventeen patients have recovered.

Hodgkin's Disease in the Aged—Sailer presents a case of Hodgkin's disease with necropsy in a white man aged 77. A series of seven other cases all macroscopically proved with

necropsy in ten, are summarized. Of the seventy-four patients, twenty-six ranged from 40 to 77 and forty from 20 to 40 years of age. There is nothing characteristic in the onset, clinical progress and duration of the disease in the latter decades to distinguish it from that occurring in earlier age periods. The anatomic distribution and histology of the lesion are essentially the same in the two groups.

Maternal Age at Conception of Malformed Children—Murphy studied the data dealing with the ages of 570 mothers at the births of 607 congenitally malformed children and at the births of 1,583 normally developed siblings. In a study of 466 of the mothers, each having at least one normal and one defective child, it was found that the average age at marriage was 21.1 years, at the birth of the first normal child 23, and at the birth of the first defective child 28.4. The proportion of defective to normal offspring at different maternal ages was found to be (1) lowest when the mothers were between 20 and 25 years of age, (2) more or less constant when the mothers were between 15 and 30, (3) increasing from year to year when the mother had passed 30, and (4) greatest after the mothers had passed 40 years of age, at which time the ratio of defective to normally developed children was approximately three or more times that noted before the mothers were 30. From this study and from a previous one, it is concluded that congenital malformation is most likely to afflict the child if it is the fifth or later in the order of birth in the family, if its birth occurs after the mother is 30 and especially if after she is more than 40.

A New Pathogen of Genus *Listerella*—Burn asserts that a new species of organism belonging to the genus *Listerella* was first obtained from a new-born infant in February 1933. One year later a similar organism was recovered from the blood in two cases of fatal illness in infants and soon thereafter a fourth organism of the same type was isolated at necropsy from the meninges and viscera of an adult. The organism has been grown by the usual culture methods and has been demonstrated readily by the Gram stain in the various tissues. In all four cases the anatomic lesions involved the liver and in the three cases in which the central nervous system was examined lesions were revealed in the tissues. Since this bacillus is markedly hemolytic on blood agar plates and in blood broth and since it has a tendency to form short chains in meat infusion broth, particularly when freshly isolated from the tissues, it may be mistakenly called a *Streptococcus haemolyticus*. It has some of the characteristics of the diphtheroids and consequently may be overlooked as a nonpathogenic organism. Through the courtesy of Schultz, Terry, Bryce and Gebhardt, Jones and Little and Seastone it has been possible to study transplants of their strains and they have been found to be identical, both culturally and serologically, with those isolated from the four cases that the author encountered. A possible source of the infection in man through the milk supply is suggested in view of the isolation of the same organism in suppurative meningitis of cattle.

Atrophy of Adrenal Cortex with Intranuclear Inclusions—Weiner reports a case in which intranuclear inclusion bodies were found in the cells of the adrenal cortex. The apparently sudden onset of a disease certainly not primarily functional, following trauma with no evident physical consequences seems difficult to understand. However that terrific emotional strains or minor accidents will frequently precipitate an Addison's disease associated with 'atrophy' as well as with tuberculosis of the adrenals is evident from a review of the literature. The fact that the blood pressure was apparently normal until the terminal crisis is not remarkable and has been noted frequently enough. The value of this as a clinical

differential point between 'atrophy' and tuberculosis has been denied. The pathologic features of the case, except for the nuclear inclusion bodies, fit completely the numerous descriptions given by various authors. Although vacuolar degeneration, disappearance of the cytoplasmic granules and diminution in the number of the basophil cells of the pituitary are reported, serial sections showed a normal appearance. Although no history of the classic symptoms of diarrhea was obtained, the fresh petechial hemorrhages, in addition to the numerous macrophages heavily laden with old blood pigment seen in the tunica proper of the intestinal mucosa offer presumptive evidence of intestinal involvement. It has become clear that typical Addison's disease can be produced by the destruction of the adrenal cortex alone. The selective involvement of specific cells associated with a disease process, the slow necrosis hyperplasia and hypertrophy of these adrenal cortical cells the apparently secondary inflammatory reaction and the relatively insignificant degree of fibrosis, in addition to the finding of intranuclear inclusions, offer presumptive evidence at least for another etiologic interpretation than syphilis tuberculosis congenital hypoplasia 'cytotoxins' circulating in the blood and chronic inflammation.

Double Human Pregnancy with Single Corpus Luteum—Wieman and Weichert secured the material for their study at the necropsy of a woman aged 25 dead of a bullet wound in the abdomen. It consists of a pregnant uterus, approximately twice the size of a normal nonpregnant one and of tubes, ovaries and the upper part of the vagina all of which were removed four hours after death. The uterus was found to contain two male embryos but since no record of the last menstruation was obtained the duration of pregnancy is

unknown. In arriving at a final decision as to the zygotic origin of the embryos, the following facts have to be properly evaluated: a single corpus luteum of pregnancy, two chorions partially united by an intermingling of their villi and two widely separated implantation sites. The last two factors strongly point to a biovular origin of the embryos. On this basis the presence of a single corpus luteum would mean that the two ova came from the same follicle and that the sexual identity is only coincidental, since each ovum would have been fertilized by a different spermatozoon. The differences in crown-rump lengths of the embryos and in the lengths of the external genitalia may be significant for such an interpretation. In view of the conditions a monovular origin could be maintained only on the assumption that the separation of the embryo into two parts occurred before implantation. This is highly improbable because it is generally believed as concluded by Arey, that mammalian monozygotic twins do not arise by the separation of early blastomeres. The common chorion which all twins of this sort possess indicates that separation must be subsequent to the period when the cleavage group is differentiated into an inner cell mass and outer shell of trophoblast. It is therefore concluded that the embryos are biovular in origin and that the two ova came from a single follicle.

Operative Exposure of Facial Canal.—Tremble and Penfield report a case of operative exposure of the facial canal with removal of a tumor of the greater superficial petrosal nerve. No other description of a perineurial fibroblastoma arising in the vicinity of the geniculate ganglion is to be found in the literature. The presenting symptom was facial paralysis. But preliminary tests localized the site of interruption to the genu of the facial nerve and exploration was undertaken with a view to a possible end to end suture within the petrous bone. The operation was carried out under tribrom ethanol in amylene hydrate and a locally applied anesthetic. The same incision was made as for a radical mastoid operation except that it was extended a little above and below. The whole tip of the mastoid process and the vaginal process of the external auditory canal was removed. The cells over the lateral sinus were uncovered. The middle ear was opened from behind by enlarging the aditus ad antrum and removing part of the roof of the external meatus. All the bone below the horizontal semicircular canal and as far as the stylomastoid foramen was taken away. The whole canal was uncovered with exposure of the facial nerve. To get a better exposure of the nerve some of the bony floor of the middle fossa was removed. The facial nerve was identified again at the bend and traced along its horizontal course. At a point about 4 mm from the bend and just above the oval window the nerve was involved by a vascular mass of tissue which proved to be a new growth. On removal of the root of the middle ear a tumor herniated into the opening. It extended through the bone from the facial canal to the subdural space following the canal of the greater superficial petrosal nerve. As much of the growth as possible was removed. During this procedure the incus was gently taken away with the curet and later the malleus and the drum. The tumor was curetted out and the seventh nerve left exposed. A low incision of the nerve capsule. Finally the eustachian tube was curetted so that it would close off with a view to future complete interruption of the tumor. At no time was there a leakage of cerebrospinal fluid. The wound was closed with the staples and the external auditory meatus left open as in a radical mastoid operation. It was decided not to make an

anastomosis of the seventh nerve to the twelfth, as it seemed possible that the removal of the tumor would allow the seventh nerve to regenerate. They urge that such an exploration should be carried out in many cases of paralysis of the facial nerve with a view to (1) relief of the pressure on the facial nerve, (2) direct suture of the nerve or (3) facial-hypoglossal anastomosis, as indicated by the operative observations.

Tissue Lymphocytes in Prognosis of Lymphogranulomatosis.—Rosenthal investigated the role of the lymphocytes and the lymph nodules of the lymph nodes and spleen and the filiation thereto of the prognosis in Hodgkin's disease. Sixty-three cases were studied in thirty-nine of which biopsies had been made before roentgen treatment was begun. In twenty-nine instances, tissues were available for postmortem examination. In fifteen of the latter instances there had been no roentgen treatment. The duration of life after the onset of Hodgkin's disease was found to be proportional to the predominance, subordination and absence of lymphocytes and lymph nodules in the lymph nodes. The average duration of life for groups of patients showing the three types was 4.35, 2.29 and 1.14 years, respectively. The effect of roentgen treatment on involved lymph nodes is thought to be (1) a decrease in the number of reticulum cells with pyknosis, karyorrhexis and necrosis or an abnormal reaction of such cells with bizarre shaped mitotic figures and irregular giant cell formation (2) a decrease in the number of lymphocytes and lymph nodules (3) a proliferation of fibrocytes with dense connective tissue formation and hyalinization if the original destructive phenomena are overcome. A marked decrease in the number of lymphocytes and lymph nodules was evident in the spleen and lymph nodes in all cases (with or without roentgen treatment) on postmortem examination. This was true whether the organ was involved by the process or not and was explained by the "indirect action" of the products of destruction of tissue entering the blood stream. Some method devised to stimulate the lymphoid elements of the body might aid in staving off the progress of the disease.

Hyperpyrexia in Bronchial Asthma.—Phillips regards hyperpyrexia in bronchial asthma as a most valuable adjuvant in conjunction with other methods for correcting existing physiologic and clinical abnormalities. At first he produced and maintained high temperatures for long periods but later lower temperatures were maintained for from four to five hours. At least ten treatments weekly or biweekly must be given for any lasting results. Lower temperatures shorter intervals and more frequent treatments have been found to be of value. This is illustrated by a case of two years chronicity in which treatments were shortened and continued up to a total of thirty-five in the third year the patient demonstrated an almost spectacular rapid improvement. It therefore becomes evident that first reports appearing in the literature covering one or two cases in which from one to three treatments each were given are of no conclusive value. It is not surprising that some of these

men have abandoned hyperpyrexia as worthless. At present the author has under observation a group of patients in whom the temperature is elevated to only 101 or 102 F for forty-five minutes daily. The present indications are that this technic might prove to be the most appropriate. With this method one can treat cases ambulatorily and increase the total number of treatments indefinitely to fit individual needs. At these temperatures, general oxidation and metabolism is enhanced and the patient is hardly inconvenienced. The therapeutic possibilities of hyperpyrexia have only been touched on.

Diagnosis of Diseases Causing Hematuria—Bechtold declares that, when it is thoroughly realized that hematuria may be the first, the last and almost the only symptom of a malignant condition of the bladder and in 54 per cent of adult renal neoplasms the initial symptom it is obvious that no one is justified in passing lightly over this important observation. These patients should be immediately and thoroughly studied preferably at the time the bleeding is present. A satisfactory diagnosis may not be possible at one sitting so that it often becomes necessary to study these patients over a long period. A large group of hematurias result from new growths in the bladder. Bleeding resulting from ulcer, stone, the various types of cystitis and so-called benign papillomas can be successfully diagnosed only by cystoscopy. Bleeding is most frequent in the serious lesions of the kidney demanding early recognition and treatment, in particular tumors and tuberculosis. In the diagnosis of renal hematuria the pvelogram is almost essential. The retrograde method is the most valuable since it is quite possible that occasionally no shadow will be obtained with the intravenous method if the affected kidney does not have sufficient function to excrete the dye. The recognition of tuberculosis of the kidney depends primarily on the identification of the tubercle bacilli in the bladder or kidney urine or in both on the appearance of the bladder and on plain roentgenograms of the genito-urinary tract showing calcareous deposits in the region occupied by the kidney. Pvelograms should be made with caution as they may result in generalization of the infection. All cases of unexplained presence of red blood cells in

the urine should make one suspicious of calculus. Blood in varying amounts is a common observation in the pyogenic inflammatory lesions of the kidney, such as pyelonephritis and results from the fracture of the young blood vessels of the granulation tissue. Ordinarily, blood appears late in the disease. Bleeding from prostatic lesions and from varicose veins around the neck of the bladder resembles bleeding from the posterior urethra. Hemoglobinuria results from the transudation of dissolved hemoglobin from within the blood vessels into the urine. It occurs in various toxic conditions resulting from chemical poisoning and in the 'black water fever' of malaria and is occasionally observed after blood transfusions and after large burns. It is recognized by its characteristic red color, the urine being clear, or, if cloudy on allowing the specimen to stand the supernatant fluid retains the red color. The benzidine or guaiac tests give a positive reaction. Red blood cells as a rule are not found on microscopic examination.

Mongolism in One of Dizygotic Twins—In Jenkins' instance of mongolism the twins were of opposite sex, obviously of dizygotic origin. Other instances of the occurrence of mongolism in one of dizygotic twins have been reported and summarized. Their significance lies in the fact that the concomitant development of a normal fetus and a mongol fetus in the same uterus demonstrates that no etiologic hypothesis placing entire dependence on a humoral mechanism of the maternal blood is tenable. Such a hypothesis would be irreconcilable with cases such as these. The ready transmission of at least most endocrine hormones across the placental barrier makes it furthermore highly unlikely that the mechanism of the production of mongolism is humoral at all. When mongolism occurs in identical twins both twins are affected. The author believes that these facts may be reconciled with his hypothesis that mongolism is due to the fertilization of an ovum the viability of which has been diminished by its age, or with the hypothesis of Rosenau that mongolism is due to foci of tissue change in the ovary, perhaps scars marking the sites of old ovulations.

*Infection and Intoxication: Their Influence on Hemoglobin Production in Experimental Anemia F S Robscheit-Robbins and G H Whipple Rochester N Y—p 767

Infection and Intoxication—Robscheit-Robbins and Whipple deal with infection and a variety of intoxications which do or do not modify the production of hemoglobin and red cells in experimental anemia in dogs due to blood loss. When clinical anemias develop in association with infection the tendency is to explain this abnormal state of the blood on the basis of blood destruction or of lack of absorption from the intestine. The experimental data indicate that the essential factor is a disturbance of the internal metabolism which is concerned with upbuilding of the large hemoglobin molecule. There is no evidence of any significant red blood cell destruction in certain experiments and strong evidence that the absorp-

tion of food constituents is normal. Accelerated metabolism due to thyroid or dinitrophenol does not modify hemoglobin production in standard anemic dogs. Endometritis lasting many weeks will profoundly reduce the production of hemoglobin in the standard anemic dog. A sterile abscess also will diminish the production of new hemoglobin in the anemic dog when liver is being fed but particularly during fasting periods when the usual abundant production of new hemoglobin is reduced to zero. Impaired absorption can be excluded as a factor of any significance in experiments in which food consumption is 100 per cent digestion normal and body weight maintained. Destruction of red cells can likewise be excluded as of any significance in experiments with the sterile abscess in a fasting period, as the freed hemoglobin would be promptly turned over by the anemic dog to appear in the subsequent weeks as new hemoglobin. These experiments point to a disturbance of internal metabolism related to hemoglobin building in the body as responsible for the inhibition of hemoglobin production under these conditions. The same factor is often of importance in human disease.

Allergic Disorders in Childhood—Adams states that in asthma due to extrinsic factors, to infection or to both, there are fairly characteristic clinical types (patients sensitive to an inhalant or to food or to both children with negative skin tests whose asthma is thought to be of infectious origin and children in whom infection and extrinsic protein sensitization play more or less equally important parts) each requiring a different approach for successful treatment. Mixed stock vaccines have a real use and give fairly consistent results in properly selected cases of asthma. In order to obtain good results treatment of allergic manifestations must be given over long periods of time. Various secondary manifestations in allergic children such as sinusitis, urticaria or angioneurotic edema may usually be ignored in the expectation that successful treatment of the chief complaint will rid the child of the secondary conditions. Testing each patient by scratch intracutaneous and passive transfer methods is well worth the time consumed. The scratch test used alone is not reliable. It is essential to test clinically all allergens giving positive skin reactions before judging them significant. The reactivity of the skin itself varies with the individual and must be taken into consideration in reading reactions. Constitutional reactions to intracutaneous tests need not occur in pediatric allergy practice.

Enuresis—Weiss states that: 1. The economic status of the family of enuretic children is important since enuresis occurred more frequently in children from families in poor financial circumstances. 2. The tendency for enuresis occurs more frequently in children of lower intelligence. 3. Enuresis occurs most frequently in the age group between 6 and 9 years and in families of three or more siblings. 4. Childhood diseases as a factor in producing enuresis must be considered in relation to the emotional disturbance arising incident to the illness. 5. Children with enuresis in most cases are affected by tears.

The incidence of fear indicates that these children are suffering from a neurosis. 6. Two personality groups may be differentiated, depending on whether the enuresis has continued from infancy or began in childhood. The children of the first group are characterized by passivity, while in the latter group the children are characterized by hyperactivity and aggressiveness. 7. Parental overprotection by preventing the child from becoming independent is an important factor since it leads to the production of protest reactions. 8. Enuresis occurred in association with other complaints of a behavioristic nature, such as stealing, lying and temper tantrums, more frequently than as the only symptom. If these complaints are to be considered as protest reactions, enuresis may also be in the nature of a protest reaction.

Summer Tetany and Serum Calcium—During July and August 1935, when there was practically no interruption of sunshine by rain, clouds or smoke, Fredeen and Neff saw two Negro infants with repeated convulsions. Some evidences of rickets suggested the possibility of tetany, and for these reasons calcium and phosphorus determinations were run as checks to the treatment. The calcium and phosphorus levels were low at the same time in the first case, possibly as a result of some variation in the mineral balance of the diet at the time. The factors that explain the development of the tetany are the deeply pigmented skin, the susceptible age, the presence of untreated rickets, the previous winter and incompletely cured rickets during the short period in March when there was about the usual amount of sunshine. Then came the period of exceptionally rainy and cloudy days in April, May and June when the infants were more completely covered with clothes than usually at this time of year. That the amount of ionized calcium in the circulating blood is low because of an incomplete diet and the supply depleted during this period of inadequate exposure to sunlight by the withdrawal into the bones of the healing rickets seems a logical conclusion as to the production of tetany in these infants.

Effect of Dinitrophenol on Rate of Alcohol Metabolism—Newman and Tainter gave dogs alcohol intravenously and dinitrophenol intramuscularly and compared the rates of fall of blood alcohol concentrations for periods when the animals breathed room air and periods when they rebreathed from a closed system. When elimination of alcohol from the lungs was prevented by rebreathing the hyperventilation of dinitrophenol did not modify the rate of fall of blood alcohol but when the dogs breathed into room air, its elimination was doubled. A similar degree of hyperventilation, produced mechanically in a dog not receiving dinitrophenol resulted in an increased rate of fall of blood alcohol similar to that in hyperventilation due to dinitrophenol. Therefore the increased rate of disappearance of alcohol from the blood after dinitrophenol is due not to the increased rate of metabolism nor to the increased temperature but to the hyperventilation.

Antivirus Treatment of Gonorrhea—Sherman treated 400 male cases of gonorrhea, in 200 of which instillations were administered of various antiseptic solutions urinary sedatives prostatic massages and the usual symptomatic treatment accepted by most physicians, and in the other 200 a combination of antivirus, vaccine and prostatic massage. The antivirus used was a product based on Besredka's work. It contains the antivirus principle of gonococcus, streptococcus and staphylococcus, combined with a vaccine made from these organisms and suspended in an inert vehicle. The vehicle used does not have any bactericidal properties it is neutral in reaction and has no effect on mucous membranes. The preservative used was a 1:10,000 mercurial solution, with little if any bactericidal action in the urethra. The patients were instructed to inject this solution into the anterior urethra each day, as supplemental treatment multiple, simultaneous, subcutaneous injections of a mixed stock vaccine were administered. Prostatic massage was not started until after the urethral discharge had entirely disappeared. Of the entire group 305 patients completed the prescribed treatment and were discharged as cured, but the patients who were treated with antivirus made better progress. The urethral discharge stopped and the first negative prostatic smear was obtained two weeks earlier in the cases in which antivirus was employed, and the first negative prostatic smear of a consecutive series of five was obtained, on an average, 31 weeks earlier. The average duration of treatment necessary to effect a cure also was 49 weeks less in the group treated with antivirus than it was in the cases in which the patients were treated with antiseptic solutions alone. The complications that arose in the course of the treatment were more than three times as frequent among the patients who received ordinary local treatment as among those who were given antivirus. Prostatitis developed in fourteen of the former cases epididymitis in three vesiculitis in one and lymphadenitis in one. In the latter group of cases prostatitis developed in only one epididymitis in three and lymphadenitis in one. The persistent regular application of antivirus solution to the tissues involved and the subcutaneous injection of gradually increasing amounts of vaccine develop a local cellular immunity as well as an increase in the general immunizing forces of the body. These results coincide with the observations of other investigators. In spite of the fact that the patients who were treated with antivirus had a larger number of complications at

the time of their admission to the clinic than did those who received ordinary treatment, progress was more rapid and satisfactory.

Fever Therapy in Treatment of Gonorrhea—Ormond used fever therapy in the treatment of twenty-one attacks of gonorrheal urethritis in twenty patients. In only two of fifteen ambulatory patients did complications arise during treatment but no complications developed in the patients undergoing treatment in the hospital. The treatment nearly always caused a prompt and striking decrease in the urethral discharge, and in cases in which the patients completed the treatments the course seemed shorter than it usually is with the ordinary forms of treatment. Arthritis and epididymitis yielded promptly, and in the one case of ophthalmitis the condition cleared up after one treatment. The older or more chronic lesions seemed to respond more promptly and more completely than did the recent or more acute lesions. This may mean that the patient's immunity, which was produced during the course of the disease had attenuated the organisms and rendered them more vulnerable to heat. Temperatures as high as 107°F have in most instances been well tolerated. An interval of three or four days between treatments is best. The duration of a treatment should not exceed six hours. In the cases in which acute lesions were cured, the most common number of treatments was five. The treatment is not free from danger, as deaths have occurred in its course. In the future, some change in technique or additional therapy will possibly enable this method of treatment to produce rapid, safe and certain cure. In long continued chronic lesions and in the presence of complications, the author believes the method will be found of great value.

Operation for Double Abductor Paralysis—Lore bases his procedure on what would happen if the anterior commissure or the arytenoid was removed and transferred to a point at which the cord would be more external. The interior of the larynx was exposed by means of a thyrotony incision, extended into the thyrohyoid membrane in the form of a V shaped incision. Then a small bladed knife was plunged through the floor of the ventricle, about three eighths inch from the edge of the cord, and coming out about three-eighths inch subglottically. The knife in this position was carried posteriorly toward the arytenoid, cutting parallel to the vocal cord. When the vocal process was reached the knife was carried internal to it, cutting the attachment of the vocal cord from it, until the posterior commissure was reached, at which point the cord was severed. The arytenoid was then dissected and removed. The tissue subjacent to the detached cord was removed down to, but not including the perichondrium. The vocal cord was then put back in its original position and anchored to the surrounding tissues by means of sutures. The result is to transfer the posterior end of the cord attachment externally. This may be kept in place by packing the inside of the larynx or by a bag inflated with air.

Readjustments Following Pneumonectomy—Rienhoff points out the compensatory changes occurring in the thoracic cage and its contents after total and partial pneumonectomy and the total absence of immediate or remote respiratory or circulatory embarrassment following these procedures. The study is based on an analysis of thirty-six cases in ten of which a complete pneumonectomy was performed. In twenty-four of the remainder only a part of the lung was removed and in two a posttraumatic atrophy of the left lung had occurred. His experience teaches him that thoracoplasty or the resection of ribs may be given up certainly as a primary procedure and that in all probability, particularly in clean cases it will be unnecessary to perform any type of thoracoplastic operation. It would also seem that it is unnecessary to do a phrenectomy before or during the operation of total or partial pneumonectomy. For it is the piston action of the diaphragm on that side against the rigid intact wall of the thorax on both sides that brings about the so necessary expansion of the remaining lobes following partial pneumonectomy and it is as a rule either completely or practically immobilized on the side operated on for some time following total pneumonectomy. It seems that at a later date the activity of the diaphragm on the side operated on returns with the filling of the thorax by the dilatation of the contralateral lung. Hence it follows that interference with the normal anatomic or physiologic condition of the thoracic parietes after total or partial

pneumonectomy may be unnecessary, if not actually harmful. It is of course advisable not to drain the remaining empty space following total pneumonectomy, because this is immediately filled, as shown, with a coagulated mass of plasma, which undergoes later organization with the production of a fibrous tissue mass that occupies a space of greater or less size, depending on the cavity that eventually has to be filled. Not only in total but also in partial pneumonectomy, if the remaining lung undergoes a compensatory dilatation, this multiloculated cystic mass of fibrous tissue is compressed by the encroaching lung or lobe and gives way as the space is occupied by the gradual enlargement of the remaining lung tissue, the final result being that the space which normally would be occupied by lung but is not becomes filled by this labyrinthine cystic, fibrous tissue body. This may, as it is in cases of total right pneumonectomy, be so great as to occupy the entire remaining thoracic cavity, or it may fill only a small portion

*Carcinoma of Stomach in Young People Report of Case with Spleno
megaly W J Bruckner New Haven Conn—p 523

Carcinoma of Stomach in Young People—Bruckner reports a case of carcinoma of the stomach in a girl, aged 20 years, in whom, because of the prominence of the anemia and splenomegaly, attention was directed almost wholly to diseases of the spleen. In a total of 22,759 cases reported from various sources the incidence of gastric cancer in young subjects was found to be 0 per cent in the age group up to 10 years, 0.06 per cent from 10 to 20 years and 1.17 per cent from 20 to 30 years of age. In young people (26 years or less) the etiology of carcinoma of the stomach is particularly obscure. Chronic gastric irritation, considered by many a primary or contributory cause in older persons, seems highly improbable in these younger people. Heredity has often been claimed to be an important etiologic factor. Multiple cases of gastric cancer in one family are often cited. However a review of the patients less than 20 years of age fails to substantiate this point of view. There is usually no history of other neoplasm in the family, sometimes the family history is not known, and only rarely is there knowledge of the presence of cancer. It has been suggested by Jaffe that teratomas may arise in the stomach and possibly gastric cancers may arise from the teratoma in the so-called congenital cases. As with older people, males are more often affected than females and in about the same proportion of two to one. The medullary type of carcinoma sometimes with the formation of glands is usually found. The scirrhous type occasionally occurs and the colloid and plastic limitis types are uncommon. Most of the tumors are located in the pyloric region. A few are found along the lesser curvature and in the cardia. The greater curvature of the stomach is rarely invaded. The disease most often simulated is peptic ulcer. In nearly all cases, the finding of carcinoma is an accidental and unexpected event. Most reviewers agree that there is a sudden onset, rapid course, persistent fever and progressive anemia. When observed, the anemia has always been of the hypochromic type. There are no reported cases with a hyperchromic, macrocytic anemia which is well known to occur though uncommonly found in older individuals. Achylia is commonly not present. The amount of free acid tends to be normal or slightly low. An abdominal mass is felt only infrequently. The other features of these cases do not seem to differ from those found in later life. The outlook is uniformly hopeless. There is no reported cure on record and no patient seems to have lived longer than three years. It has been emphasized many times that the extended use of roentgen studies earlier surgery and the wider use of radiotherapy would alter the prognosis. Nevertheless in every case thus far the lesion was inoperable when cancer of the stomach was first suspected.

Treatment of Varicose Veins—Payne attempts to assess the methods employed in the treatment of varicose veins. His experience is based on more than 1,000 consecutive cases. The sex distribution of the cases gave a ratio of four females to one male. A family history of varicose veins was present in more than 50 per cent of the cases. In women varicose veins tend to appear during the periods of endocrine stress—puberty, the early years of child bearing and the menopause. Numerically the group in which the veins first appear during pregnancy is by far the largest, usually during the second or third month. Varicose diseases are invariably progressive, arrest is unusual and natural cure is rare, apart from that which occasionally follows acute phlebitis. Primary varicose veins may be true varicosities, ectasia or varicules. Secondary varicose veins develop as the result of obstruction of the deeper veins and are usually associated with lymphatic obstruction. In all cases an accurate history and a careful clinical examination are essential if appropriate treatment is to be carried out and the best results are to be obtained. It is suggested that the most frequent type of phlebitis in varicose veins is in reality a thrombosis. The ideal injection medium must be nontoxic, in the doses used it must produce no undue pain during injection, it must be free from local or general dangers, and it must be introduced in such a way that no important physiologic changes may follow the obliteration of the injected veins. Injections should begin in the most distal veins working gradually up the limb. In varicose ulceration rest in bed or some form of external support may result in temporary cure and a permanent cure may follow injection or excision of the affected veins. In the treatment of phlebitis the small thrombotic lesions are best dealt with by putting the limb in elastoplast and allowing the patient to walk, in these, uneventful recovery is the rule. In the case of spreading phlebitis elastoplast treatment should be similarly carried out but it is often found that arrest of the condition is not brought about unless the patient is in bed. Operation offers the best prospect of cure in cases of this type in which huge varicose veins have become extensively thrombosed as the result of the phlebotic process. The introduction and the development of injection methods have overshadowed operative measures to such an extent as to suggest that these actually have no place in treatment. But there are definite indications for operative intervention. In the patient with uncomplicated varicose veins, certain features may indicate the advisability of operative treatment either alone or more often in conjunction with injections. 1 The veins may be of such colossal size that the discomfort and length of time involved in the process of sclerosis will make operative treatment simpler and quicker. 2 The whole saphenous tract may be varicosed and owing to the incompetence of the valves the reflux of blood may be so great that thrombosing solutions will have little or no effect. 3 The condition of ectasia rather than varicosity may be present in which case it is difficult to obtain thrombosis.

Epidemic Cervical Adenitis—Simpson discusses an epidemic of cervical adenitis consisting of two children and four adults in one household and another child who shared the same

desk at school. The onset was usually acute, although it might be anticipated by a few days malaise. The illness proper was ushered in by a sharp rise of temperature to 103 F, severe headache, drowsiness, photophobia (frequently with slight conjunctivitis), prostration and rapid painful enlargement of the tonsillar, cervical and even occipital glands. Slight sore throat was usual, although not invariable, and in no case was the local inflammation of the throat more than relatively mild compared with the adenitis. The glands might become palpable within a few hours but sometimes were not a prominent feature for some days. They were hard discrete and tender, and the increase in size was usually so considerable as to render the adenitis the presenting feature of the illness. The glands began to subside at the beginning of the second week. To minimize pain the neck was held in a fixed position and acute torticollis might be simulated. Shivering or rigor on the first day was usual but not invariable and recurrent rigors, as in the cases described by Miller were not a feature. The temperature remained high for ten days or more, being from 102 to 104 F in the evening and a few degrees lower in the morning. The pyrexia was associated with free perspiration sometimes very profuse. The pulse was usually but not invariably, disproportionately slow compared with the temperature. Transitory remissions were not uncommon when well being with a normal temperature was a feature suggesting a rapid recovery, only to be followed a day later by complete recrudescence. Prostration within the first few days was the rule and the patient's general condition usually gave rise to anxiety. Headache was usually severe, being occipital generalized or bandlike in distribution. Diarrhea and slight colicky abdominal pain was a feature in four patients. Convalescence was associated with weakness, inertia and some anemia. The incubation period would appear to be about six days or less, the duration of the acute phase about ten days and of the total illness about three weeks. The blood counts in the present series and those in Cameron's and Miller's cases are too few to exclude glandular fever, but they do suggest a different disease in that a relative lymphocytosis was never present. In one patient of the present series there was enlargement of the axillary and inguinal glands, which Cameron states may be involved in glandular fever but not in epidemic streptococcal adenitis. An important diagnostic point in the present series was the complete negativity of the agglutination test for glandular fever. The author is of the opinion that neither the streptococcus nor any other organism is yet established as the etiologic agent.

Concentration of Lead in Urine—Shiels determined, by Taylor's method the concentration of lead in the urine of twenty-nine subjects of compensatable lead poisoning and of eighty-five subjects who were fit and exposed to generally similar hazards. The average value in the case of fit subjects was 0.12 mg per liter of urine. The average value in the case

of subjects suffering from compensatable lead poisoning from whom samples were taken while they were still exposed to the hazard or within a few days of leaving it, and who had undergone no treatment previous to reporting sick, was 0.23 mg per liter. Out of 114 subjects, twenty-four showed concentrations equal to or greater than 0.2 mg per liter, seventeen of these, or 70.8 per cent, were suffering from compensatable lead poisoning. Thirteen subjects showed concentrations equal to or greater than 0.25 mg per liter; twelve of these, or 92.2 per cent, were suffering from compensatable lead poisoning. Of the subjects with compensatable lead poisoning, 50 per cent showed urinary lead concentrations equal to or greater than 0.25 mg per liter. The results confirm those of Kehoe, Thamman and Cholak, who considered that lead poisoning could be expected when the urinary lead excretion was 0.21 mg per liter, and of Brown, who found that 50 per cent of the subjects of lead poisoning had urinary lead concentrations above 0.2 mg per liter.

Infarcts and Thromboses in Necropsies—Cleland asserts that in the 3,000 postmortem examinations at the Adelaide Hospital infarcts were encountered in 209: 119 in the lungs, sixty-four in the kidneys, fifty-six in the spleen, two in the adrenals, two in the liver, three in the small intestine and one in both testes. Massive pulmonary embolism occurred in forty-one instances; thromboses in large vessels in seventy-eight; antemortem thrombi in the chambers of the heart in sixty-four and infarcts of the wall of the heart in thirty-three. In thirty-three of 109 cases in which infarcts in the lung were present there were infarcts in other organs as well; the majority of these being in the kidneys (twenty-four cases). Infarcts in the lung were associated with valvular disease of the heart in thirty cases, and with hypertrophied and dilated hearts not due to valvular disease in thirty-six, and were due to a detachment of clots from large systemic veins in twelve. In typhoid there were two examples of infarcts in the lungs. In the two cases of infarcts of the liver, one patient was a woman of 37 who developed *Staphylococcus aureus* pyemia after an operation for repair of the cervix and who showed portal pyemia with abscesses and infarcts. The other was a man, aged 32, with malignant endocarditis of the mitral valve and infarcts of the lungs, kidney and spleen as well. Infarcts of the kidneys were associated in two thirds of the cases with infarcts elsewhere. In twenty-seven of the sixty-four cases there were infarcts of the spleen. Malignant endocarditis was responsible in twenty-nine of the sixty-four cases. In half the cases in which infarcts of the spleen were present there were infarcts in other organs. When there were infarcts elsewhere, malignant endocarditis was the usual source of the emboli. When there were infarcts only in the spleen, malignant endocarditis was responsible for only about one fifth of the infarcts. Bilateral infarcts of the testes were recorded in a man of 29 with a hypertrophied and dilated heart from mitral stenosis and an adherent pericardium with red granular kidneys.

Tuberculosis with Relation to Meningitis—In his summary of 300 necropsies Scott found that, apart from nine cases in which brain tuberculomas were found, the meninges showed tubercles in ninety-three of 225 children less than 10 years of age and in thirty-five of the seventy-five more than 10 years of age. Between the ages of 10 and 20 years there were three among ten, leaving thirty-two among sixty-five adults more than 20 years of age. The distribution of the milia differed

as regards the frequency with which they were found in children and in adults. Not once among the children were tubercles found along the Sylvian fissures when not seen elsewhere, and only once in the whole series, and that was the case of a man of 27 with cavities in both lungs, widespread bronchopneumonic phthisis and adherent thickened pleura, but no signs of involvement of any other viscus except for the tubercles, which were few, along the left fissure of Sylvius.

Pathologic Anatomy of Human Kala-Azar—In a study of thirty-one cases of kala-azar coming to necropsy, Hu found that besides the parasitization and great increase in number of the cells of the reticulo-endothelial system there are other changes. 1 There is frequent occurrence of extramedullary blood formation on the dural surface with secondary growth of new bone on the inner surface of the calvarium in the corresponding areas. 2 Myelocytic hyperplasia is especially striking after the parasites and their containing cells have disappeared. The young myeloid cells, especially the myelocytes are greatly increased whereas the metamyelocytes and leukocytes are decreased in number; the normoblasts are in most cases either not greatly increased or even probably decreased. 3 There is an increase of plasma cells in the spleen and bone marrow, which may remain for a considerable time after the parasitized cells have disappeared. A positive diagnosis of kala-azar can not be made without the finding of parasites. As a result of this study certain anatomic criteria are found which when considered together will make the diagnosis of kala-azar reasonably though not absolutely, certain in the absence of parasites.

Infantile Spinal Progressive Muscular Atrophy—Cheng and Hu believe that possibly in infantile spinal progressive muscular atrophy (Werdnig-Hoffmann's disease) and in congenital amyotonia there is a factor as yet unknown which acts in the fetal life to disturb the normal development of the nervous system. This process may be arrested in the postnatal period giving a picture of arrest of development or may continue after birth to give rise to degenerative changes. Based on this hypothesis only the four cases reported by Spiller, Councilman and Dunn, Leimboulet and Baudoin and Menges which pre-

sented a normal nervous system, do not belong to this group and are probably the only examples of a primary muscle disease a congenital form of primary myopathy. Since Oppenheim in his original article thought that congenital amyotonia is a primary muscular disease with a tendency toward gradual improvement, it seems reasonable to suppose that only these four cases should be considered as true Oppenheim's disease. A primary disease or degeneration of the muscles will certainly not be able to produce such profound changes in the nervous system as are seen in spinal progressive muscular atrophy. The muscular picture does not have to be explained on the basis of arrested development. It seems reasonable to suppose that the muscular changes in this condition are secondary to nervous changes that take place in the antenatal as well as postnatal periods. What produces the primary changes in the nervous system cannot be answered at present. Besides changes in the spinal cord and in the muscles, several workers have described changes occurring in one or the other internal secretory glands: sclerosis of the thymus and of the thyroid by Councilman and Dunn, increase of the interacinar epithelium of the thyroid by Lewis and a deficiency of chromaffin cells in the adrenals by Griffith. The authors have found atrophy of the adrenals and hyperplasia of the thymus. The significance of this is uncertain since such changes are found in only a few cases and the present knowledge of these internal secretory glands does not aid in postulating a correlation.

Gouty Tophus—Cornil and Paillass discuss the pathogenesis and histologic reaction of the gouty tophus. There are two changes which are important, namely, vascular alterations and the so-called tophic infarct. After the exudative inflammatory attack manifested by clinical gout, major vascular lesions are produced. These are endothelial hyperplasia and fibroblastic sclerosis, which result in progressive obliteration of the lumen of the vessel. The succeeding thrombosis and the infarct are derived from an area of ischemic necrosis. The tissue attrition constitutes the point for the crystalline precipitation. The urate crystals act as a foreign body and contribute to the elaboration of a tissue reaction in which the reticulo-endothelial hyperplasia, macrophage reactions and lymphocytic infiltrations are the primary elements. The collagen sclerosis is a cystic sclerosis and the plain degeneration is no more than an epiphenomenon of the histologic picture. This pathogenic interpretation based on a definite anatomic foundation explains the failure of all attempts to reproduce the gouty tophus artificially. Thus subcutaneous injections of uric acid, as well as sodium biurate, have no chance to reproduce the picture because they lack at the outset of the test the principal conditions, i. e., vascular lesions and the infarct which are necessary for the pathologic end results.

Permeability of the Meninges to Arsenic Before and After Malaria—Paulian believes that the permeability of the meningeal barrier to arsenicals can be explained only by the vascular endothelial lesions resulting from syphilis in dementia paralytica. Twelve patients with dementia paralytica were examined before and after malarial therapy in an attempt to determine what changes resulted in this meningeal barrier. He concluded that permeability of the meninges for arsenic, which is absent in normal cases, is definitely increased in cases in which the barrier is injured by dementia paralytica. This increase of permeability is probably explainable by the persistence of syphilitic vascular lesions whose disturbing influence is well known. The cerebrospinal fluid shows variations in the level of arsenic depending on the time one hour after an intravenous injection it is found in the proportion of 1 to 18 mg per hundred cubic centimeters; the maximum permeability

is found about four hours after injection, from 18 to 24 mg per hundred cubic centimeters and after ten hours the level is lower. The blood also shows variations in arsenic content similar to that of the cerebrospinal fluid. After fever therapy by malaria or vaccines the meningeal permeability is considerably lowered. This fact cannot be explained by the cure of the vascular lesions and death of the spirochetes existing at this level. In favor of this fact, however, is the undeniable observation that clinical cures and prolonged remissions are often observed after this treatment. The most important practical conclusions from these studies are that in cases in which malarial treatment has given good results they are accompanied by changes in the permeability of the meningeal barrier and that investigation of this permeability constitutes one of the most important tests for the determination of improvement or clinical cure of dementia paralytica.

New Antidote Against Toxic Metals—The basis for Strzyzowski's antidote against the poisonous heavy metals is hydrogen sulfide. His method of preparation of 'antidotum metallorum' is as follows. Two liters of distilled water is heated to boiling. Two grams of sodium hydroxide is dissolved in half of this water and it is then supersaturated until cold by a current of hydrogen sulfide previously washed by being passed through a suspension of calcium carbonated water. Meanwhile, when the remaining water reaches a temperature of 50 C. 7.5 Gm of crystallized magnesium sulfate and 25 Gm of sodium bicarbonate are dissolved in it. When cool this second solution is added to the first and mixed, after having been cooled to 2 or 3 degrees below zero and finally saturated at this temperature with hydrogen sulfide gas. The preparation is placed in 125 cc flacons sterilized and cooled to as close to zero as possible. They are then stoppered with red rubber of good quality and sealed with paraffin. As prepared, the antidote is colorless at first but later develops a slight yellow tint which is an index of its good quality. Calculated as hydrogen sulfide the content in sulfur toxicologically active is more than 0.5 Gm per hundred cubic centimeters. It follows that 100 cc of this antidote recently prepared can instantly convert 4 Gm of mercury bichloride into inactive sulfur of mercury. The preparation is quite stable and the author believes that it is effective for detoxification of a large number of heavy metals such as antimony, silver, cobalt, iron, mercury and lead. When taken internally within limits compatible with physiologic functions the antidote is not toxic. Experience shows that 100 cc. taken by mouth or given by stomach tube does not produce undesirable reactions. The author himself took 0.2 Gm of mercury bichloride dissolved in 50 cc of water and two seconds later, 50 cc of the antidote. No serious complications resulted and he concludes that this antidote is a valuable addition to the treatment of heavy metal poisoning.

Hypertrophy of Palpebral Tarsus of Facial Teguments and of Ends of Limbs Associated with Almost Generalized Osteoperiostosis New Syndrome. J N Roy—p 517

Hypertrophy and Osteoperiostosis—Roy reports the case of a man, aged 47, whom he has been able to observe for ten years. His disease was characterized by a complex of symptoms consisting of a hypertrophy of the upper eyelids, hypertrophy of the tissues of the face and extremities of the limbs and a disorder of the osseous system consisting of widespread osteoperiostosis. Although appearing somewhat acromegalic, the syndrome did not fulfil any of the requirements of the latter disease. The syndrome remained stationary in the case reported for almost the entire period of observation. The author believes that this syndrome is probably of endocrine origin and most likely due to some disorder of the parathyroid glands and the hypophysis. He considers the syndrome a new disease, since he has been unable to find a similar one described elsewhere.

Cutaneous Metastasis of Gastric Neoplasm Case R Mannini—p 343

*New Technic for Amputation of Tibia with Protection of Stump by Muscular Flaps P Frassinetti—p 352

Morphologic Alterations of Trachea After Tracheotomy—Tantini and Parzani performed tracheotomy by an incision and with a window in dogs to verify the morphologic alterations that follow these procedures. The alterations consist in deformation of the canal with eversion of the stumps of the tracheal rings at the point of the incision and formation of a cartilaginous callus which results in rigidity of a segment of the canal. From a clinical point of view the several forms of tracheolaryngeal chronic catarrh from which old tracheotomized patients suffer can be considered as due to dysfunction of the tracheal canal because of rigidity of the segment in which the incision was made and to intratracheal stasis of catarrhal secretions in the sinuities corresponding to the evverted part of the canal which experiments prove to exist. No morphologic alterations of the trachea follow the tracheotomy with a window especially if the latter is made according to the size of the cannula to be used. The organ maintains the normal diameter of its lumen and the cylindric form of the canal after this operation. The reparation of tissues is perfect and the functions of the organ are good. Tracheotomy with a window is preferable to tracheotomy by incision.

Amputation of Tibia with Protection of Stump—Frassinetti's technic of amputation of the tibia is a modification of Macaggy's. The original technic, which was reported in the *Archivio italiano di chirurgia* 40 28 (April) 1935 consists in protecting the bone after resection by a muscular cushion. Macaggy prepares four flaps (two muscular and two cutaneous in apposition) as follows. A large posterior muscular flap and a large anterior cutaneous one, both larger than the diameter of the limb after resection and then a short anterior muscular flap and a short posterior cutaneous one both half the size of the former are prepared. The posterior muscular flap is placed around the surface of the resected bone and sutured to the anterior muscular flap and then it is covered by the anterior cutaneous flap which is sutured in turn to the posterior cutaneous flap. The technic results in the formation of a painless stump in which the bone especially the crest of the tibia is protected by a muscular cushion and the scar is located posteriorly which allows the use of the prosthesis without discomfort to the bearer. Frassinetti prepares only two oblique flaps in apposition (one posterior muscular and one anterior cutaneous) of the same size and larger than the diameter of the limb after resection. After amputation by the usual technic the muscular flap is placed in direct contact with the surface of the resected bone and sutured to the anterior border of the muscular surface and then covered by the cutaneous flap which is sutured in turn to the posterior border of the skin. Frassinetti's modification results in the same advantages of a painless

stump, adaptable to the use of a prosthesis and the formation of a scar located posteriorly. The technic is easier than the original one and the tissues are less subjected to trauma in the preparation of the flaps.

*Genesis of Edema F Bruno—p 58

Origin of Edema—Bruno made experiments with the aim of verifying the mechanism of production of edema. From his results and from observations of clinical cases, which he reports he states that all the different types of edema originate from only one factor either toxic or biologic, which is in relation to the primary disease. The biologic or toxic factor produces a rupture of the equilibrium between the blood and the tissues, a process of capillaritis and alterations of the tissues follow, and water and some constituents of the blood pass into the intercellular spaces and tissural lacunae, where they are retained because of alterations of the cellular protoplasm.

Apple Treatment of Diarrhea in Children—The administration of Moros apple diet in the treatment of diarrhea in children and the results were described in the *Klumsche II ochenschrift* 8 2414 (Dec. 24) 1929 (abstr. *THE JOURNAL*, March 1 1930 p 673). Further reports on the value of the treatment and results have been given in *THE JOURNAL* March 21 1931 page 987, Nov 18 1933, page 1673, Sept. 29, 1934, page 1013 and Sept 28, 1935 page 1062. Sorrentino's modification of the treatment consists in the administration of a concentrated extract of fresh ripe apples which contains the therapeutic principles of apples, especially pectin and tannic and malic acids. According to age and to the intensity of the gastro-intestinal disturbance, the patient receives daily a quantity of the extract that varies between two and four vials, the contents of which are dissolved in a cup of tea sweetened with saccharin. For the first eight or twelve hours the patient is on a hydiatic diet only. After that he may again be put on the diet proper for his age. The duration of the treatment is controlled by its effects. The author employed the treatment in fifty-one children thirty-eight infants under the age of 1 year and thirteen children ranging in age from 18 months to 3 years. The duration of the treatment in infants varied between one and four days, except in one case in which it was given for eight days. In children of the second group it varied between four and five days. Occasionally it was given for seven days. The results of the treatment being considered as a whole in the two groups were satisfactory in diarrhea of toxic alimentary origin fair in diarrhea of toxic infectious origin of mild intensity and negative in diarrhea secondary to grave infectious diseases. Diarrhea is the first symptom to be controlled the stools are formed restlessness and the gastric and humoral disturbances disappear, appetite returns and in a short time the patient begins to regain weight. The modified treatment has the following advantages over the original method. The period of exclusive hydiatic diet is greatly reduced the apple extract in saccharinized tea is palatable which makes it easy to give to children and nurslings and the extract is not expensive and can be obtained at any season of the year. The author believes that pectin is the agent of predominant therapeutic properties in the treatment.

Alkali Reserve and Heliotherapy—Morganti determined the alkali reserve in thirty-three children under the age of 3 before and after receiving sun irradiations. In the group of normal children the alkali reserve was normal before and after the treatment. In children suffering from rickets or nutritional disturbances the alkali reserve was diminished before the treat-

ment and normal after it. The normalization of the alkali reserve coincided with the improvement in the rickets, the nutritional condition and the general health of the patient. In a case of osteopsathyrosis the alkali reserve was diminished before the treatment and normal after it. In two cases of tracheobronchial adenopathy it was diminished before the treatment and was not changed by it. The author emphasizes the importance of heliotherapy in acidotic disturbances of children suffering from rickets and nutritional disturbances.

Iron and Arsenic Waters in Therapy of Lymphatism. P. Farnetti—p. 357

Honey in Diet of Infants.—Farioli substituted honey for sugar in the diet of eighteen artificially fed infants and found that because of its palatability it is well tolerated and controls vomiting, diarrhea and gastro-intestinal disturbances, thus increasing the weight and improving the nutritional condition of the infants. By a coprologic examination it is found that honey modifies the macroscopic aspect, nature and flora of the feces, which become uniformly constituted by gram-positive nonpathogenic saprophytes and fecal cocci in a small number. The pH of the feces does not become acid by the use of honey. The latter is not followed by glycosuria and the test of produced hyperglycemia after administration of honey gives the same results as that following the administration of sugar.

*Experimental Demonstration Significance and Bacteriologic and Histologic Demonstration of Bacteriuria. P. Pariscenti—p. 191

Experimental Production of Bacteriuria.—Pariscenti made experiments to ascertain the passage of bacteria from the blood through the kidney and the significance of the phenomenon. The experiments were performed in rats, rabbits, guinea pigs and cats, all of which were given intracardiac injections of bacteria (staphylococci, streptococci and the typhoid bacillus) which were recovered in the urine of the animals in about three minutes. The microscopic examination of the kidney proved that the elimination takes place through the normal glomerular rete mirabile. The renal tubuli do not intervene in the elimination of bacteria. The author's experiments are to prove that the normal kidney eliminates bacteria when the latter is present in the blood and that the phenomenon is of a physiologic nature.

Alterations of Blood by Vaccinia Dermovirus and Neurovirus.—Goyanes and Alonso Buroñ studied the alterations of the blood that follow the intracerebral inoculation of neurovaccine and the intravenous inoculation of dermovaccine into rabbits with especial reference to the behavior and significance of pathologic (toxic) granulations of the granulocytes. These granulations appear early in the course of certain infections and in an acid medium (pH 5.4) take the Giemsa stain which is not taken by normal granulocytic granulations. In the authors' experiments the blood was examined for pathologic granulocytic granulations before inoculation in the course of

the experimental infection and shortly before death, which took place spontaneously or was produced on the fourth day in rabbits that were intracerebrally inoculated with neurovaccine and on the fifteenth day in those which were intravenously inoculated with dermovaccine. There were no pathologic granulations in the blood of rabbits in either group before the inoculation. The authors state that the clinical evolution of the experimental disease is nearly paralleled by a progressive increase of pathologic granulocytic granulations, which, in grave cases affects 94 or 98 per cent of the granulocytes. The important action that the vaccinia virus, both neurovaccine and dermovaccine, has on the development of pathologic granulocytic granulations indicates the part that the mesodermal structures play in the development of the infection.

*Prandial Diarrhea in Infants. R. M. Calzada Rodríguez—p. 212

Prandial Diarrhea in Infants.—Calzada Rodríguez says that prandial diarrhea in infants is a type of constitutional diarrhea the characteristic of which is the expulsion of diarrhetic feces immediately after or within a short time of feeding. As a rule, infants having prandial diarrhea suffer also from constitutional nutritional disorders and are subjected to neuropathic and exudative diathesis and sympathetic dysfunction, with predominance of the vagus over the sympathetic. Anaphylaxis and alimentary sensitization do not intervene in the etiopathogenesis of the disease. Infections are secondary factors. They have an influence on the evolution but not on the onset of the disease. The exaggerated gastrocolic reflex is the factor involved in the mechanism of production of the disease. Dystrophy and diminution of immunity, which is exteriorized by the frequent development of infections, are the most frequent complications. The intensity of the nutritional disturbance depends on the constitution of the patient, the type of feeding, natural or artificial and the frequency of appearance of intercurrent infections. As a rule the prognosis is favorable except in patients with intense diathesis, extensive eczema, grave nutritional disorders and frequent appearance of infections, especially if the disease is of a hereditary nature. Early treatment is advisable. The dietetic treatment consists in normalization and hygiene of natural feeding. If it cannot be given, the infant is placed on a mixed natural and artificial diet, and only as a last resort is he put on an artificial diet of buttermilk, albuminated milk and soy bean flour preparations. The medical treatment consists especially in the administration of drugs having a paralyzing effect on the vagus.

Twin Pregnancy Cases. M. Vicente Moreira—p. 288

Treatment of Arterial Hypertension by Roentgen Irradiation of Carotid Sinus.—Moniz de Bettencourt and Corte-Real attempted to control arterial hypertension in twelve patients by means of roentgen irradiations of the carotid sinus. The irradiations were given in doses of 50 roentgens. Each irradiation was given in a field 6 by 8 cm over the carotid sinus, first on one side and then on the other, with an interval of three or four days between irradiations, so that irradiations on the same field were given at an interval of seven days. The tension used was 190 kilovolts and the intensity was 4 milliamperes with a copper filter of 0.5 mg and a focal distance of 30 cm. The entire treatment consisted of six irradiations, three on each side. The authors state that the treatment results in lowering of arterial hypertension, which diminishes still more after completion of the treatment. They believe that the satisfactory results of the treatment are due to a stimulative action of the irradiations on local nervous reflexes and to a vasodilating action by which favorable changes of the local circulation are produced. The latter result in improving the metabolism of the local tissues and the condition of the carotid sinus. The authors advise resorting to the treatment in cases in which the production of hypotension is indicated.

Spinal Anesthesia in Children—Echegaray and Lima have performed more than 314 operations with spinal anesthesia on children ranging in age from 3 months to 17 years. The technique is that used in spinal anesthesia in adults except that a thin needle is used. The puncture is made at the middle line with the patient either in the sitting position or in lateral decubitus, the point of injection being determined by the region in which the operation is performed. The patient lies down immediately after the injection. The authors used procaine hydrochloride either in powder or in solution. In the first case the procaine was dissolved in 2 or 3 cc. of the patient's cerebrospinal fluid taken from the puncture immediately preceding the injection. The elimination of cerebrospinal fluid is not allowed if a procaine solution is used. The doses were of about 0.0012 Gm for infants and never more than 0.0003 Gm for children under the age of 15. Certain symptoms of a bulbar type and others that appear during the operation or after it are controllable by instructing the patient to take deep respirations by permitting vomiting and in some cases by administering caffeine injections. Serious accidents do not occur during the operation or after it.

Treatment of Chronic Osteomyelitis—According to Dengler, ninety-six patients suffering from chronic osteomyelitis were treated in the orthopedic clinic of Munich between January 1932 and January 1935. All cases were of a difficult type, presenting numerous suppurative processes in various bones, associated with joint contractures. Most of the patients were treated elsewhere by numerous operative procedures. In order to evaluate the Orr and the Löhrr methods of treatment, the author selected thirty-seven patients who were operated on not later than nine months previously. Forty-one operative procedures were carried out. Of the thirty-seven patients, three died of generalized infection. Twenty-three lesions were treated by the Orr and fifteen by the Löhrr method. Twenty-three patients completely recovered, presenting no fistulas, clinical recurrence or complaints nine months after the operative intervention. Eight had small fistulas but had otherwise recovered, while small sequestrums were removed in seven at variable periods after the operation. Pseudarthroses, extension of the suppurative process into the neighboring joint or metastatic abscesses did not take place in this series. While both methods were gratifying the results with the Löhrr method were superior. The wounds healed more quickly and left less conspicuous scars. The two methods present similarity as to the technique and the underlying principle. In both the diseased bony tissue is radically removed, the bone is saucerized and the resulting cavity is filled with gauze strips saturated with petrolatum in the Orr method and with a cod liver oil petrolatum mixture (unguentolan) in the Löhrr method. Orr applies a circular plaster-of-paris cast to the extremity while Löhrr first sutures loosely the soft tissues over the operative area and then applies a cast. In both instances the dressings are changed every three or four weeks. The underlying principle of both methods is rest to the tissues and avoidance of disturbance of fresh granulating tissue. The theoretical advantages of the cod liver oil

are its sterility, its bactericidal property because of the high vitamin A and D content and its stimulating effect on the mesenchymal and epithelial tissue repair. The unpleasant feature of both methods is the saturation of the dressings and the cast with discharges from the wound. The resulting bad odor may lead to loss of appetite, vomiting and impairment of nutrition but may be at least partly overcome by the use of deodorants. Maceration of the skin is successfully prevented by the use of a thick layer of Lassar's paste.

Porphyrin in Plasma of Patients with Lead Poisoning—Vigliani and Angeleri investigated lead poisoning, because the porphyrin content is greatly increased. In nearly all cases examined by them, they detected a secondary fluorescence in the plasma. Heretofore the quantities of porphyrin have never been sufficient to permit a spectroscopic analysis. The peculiar behavior of the porphyrin toward solutions of hydrochloric acid induced the authors to study the nature of the porphyrin. In cases of new and rather severe lead poisoning, they were able to show by means of Schumm's grating spectroscope that the porphyrin in the plasma is protoporphyrin, for the absorption lines differ, that for protoporphyrin being at 632.5 and that for coproporphyrin being at 623.6. In discussing the origin of the protoporphyrin they suggest that it originates in the destroyed erythrocytes and point out that during lead poisoning the erythrocytes contain greater amounts of porphyrin than is normally the case and that they are more rapidly destroyed. The authors give descriptions of only four cases, but their observations were made on a large number of patients. They think that in some cases in which the acute symptoms have disappeared the plasma may contain coproporphyrin in addition to protoporphyrin, suggesting that a mixture of the two types of porphyrin may appear when the hemolysis is no longer severe and the liver is capable of more completely utilizing the porphyrin that is freed from the erythrocytes.

Determination of Cevitamic Acid in Urine—Jezler and Niederberger have modified Tillmans' method. They make three or at least two parallel tests each with 10 cc. of urine. Each portion of urine is placed in an Erlenmeyer flask and after being acidified with 1 cc. of glacial acetic acid, is diluted with 100 cc. of distilled water. The contents of the flask serve as a vehicle for the dichlorophenolindophenol solution, which is dropped into it from a 50 cc. buret until the resulting red coloration remains constant for thirty seconds. The result must be stated in milligrams and must take account of the total quantity of urine. The empty value should also be watched for. The titration should last only from thirty to 120 seconds, in order to avoid interference by other substances. The vehicle should be shaken mildly and continuously. Tillmans originally prescribed a pH of 7, which makes the cevitamic acid too oxygen sensitive, and the authors found that the fluid to be examined should be acidic with a pH of from 2.7 to 3. The empty value corresponded as a rule to 0.7 or 0.8 of the indicator solution. Since the amount of water increases the empty value, care must be taken that the water does not greatly exceed 100 cc. If this quantity is not sufficient to obliterate the urine's own color, smaller quantities of urine must be used. The method of titration originally used by Tillmans was rather complicated because of the preparation of the indicator solution from the dichlorophenolindophenol. This difficulty has been overcome by the use of ready prepared tablets (each corresponding to 1 mg. of cevitamic acid) which only have to be diluted in distilled water. The authors emphasize further that the titration of the urine should be done as soon after micturition as possible. For this reason they devised an apparatus which makes it possible to

perform the titration during the consultation hour or even at the patient's home. They illustrate and describe this apparatus and its use.

Determination of Morphine in Urine—Deckert describes a highly sensitive nephelometric procedure for the detection of morphine in the urine, which is prepared in the following manner. Ten cubic centimeters of filtered or unfiltered urine is transferred by means of a pipet to a beaker and is mixed with 0.3 Gm of sodium carbonate. It is heated until the first bubbles rise and then quickly cooled. Then it is poured into the shaking funnel, the beaker being rinsed with 2 cc. of water. Twenty cubic centimeters of acetic ether is added and the mixture is well shaken. After the layers have separated, the lower layer is drained off and the acetic ether is decanted through a filter into a small porcelain dish and evaporated on the water bath. In the presence of large quantities of morphine (more than from 30 to 40 micrograms), only a part of the acetic acid is evaporated. The author admits that, in case of a single shaking, only from 60 to 70 per cent of the morphine is extracted, but this percentage is so constant that the total can be found by multiplication. In order to separate the morphine from disturbing substances, the residue remaining in the porcelain dish, after having cooled, is diluted in 0.25 cc. of water with 1 drop of nitric acid (specific gravity 1.15) and 1 drop of molybdate solution (10 per cent of ammonium molybdate in water). After careful whirling of the porcelain dish, there follows filtration into a test tube through a compressed cotton plug (0.5 cm in length) placed in the upper part of the neck of a small funnel. The dish is first washed with 0.25 cc. of water and this is passed through the filter. Then the dish is rinsed with 0.15 cc. of water, which is again passed through the filter. The cotton plug is pressed down to the lower opening of the funnel so that no filtrate remains in the funnel. The filtrate is mixed with 2 drops of ammonium vanadate solution (2 per cent ammonium vanadate in water). Depending on the morphine content, a turbidity develops in the clear filtrate within a few seconds or only after several minutes. Immediately after the addition of vanadate the fluid becomes yellow, but this color pales. The maximum of turbidity is reached at the latest after twenty minutes. At this time the dilution (up to 5 cc.) with distilled water is made and the nephelometric determination follows. If this is done by means of standard solutions they should be prepared at the time of filtration through the cotton plug so that the vanadate can be added at the same time. The author emphasizes that this method permits the detection of traces of morphine in the urine even after a single administration of only 0.15 Gm. of morphine. It has the advantage that it can be made in any clinical laboratory and that it facilitates the supervision of morphine addicts.

Allergy in Tuberculosis—Zapatero Dominguez and Lopez studied in fifty-four tuberculous women, the white blood picture of the tuberculin papule of normal skin as well as an area that had been desensitized by ultraviolet irradiation. In twenty-seven cases the tests were made twenty-four hours after the skin reaction and in the other twenty-seven cases forty-eight hours after the skin reaction. A comparison of the white blood picture of the papules of normal skin with that from the finger revealed an increase in the lymphocytes and a decrease in the neutrophils in the former. These manifestations were more frequent in patients with the severer forms of tuberculosis than in those with the milder forms, that is after twenty-four hours they were more frequent in the patients of the second than of the third stage, whereas after forty-eight hours the opposite was the case. The tuberculin papules of the desensitized skin in all but six cases were smaller than the papule of the normal skin. The papules of the desensitized skin usually reach the peak of their development after twenty-four hours and thus differ from the normal Pirquet papule

which reaches its peak only after forty-eight hours. The white blood picture of the papule of desensitized skin is characterized by a decrease in the lymphocytes and monocytes and an increase in the neutrophils and eosinophils. The decrease in lymphocytes is most characteristic and to a certain extent runs parallel with the reduction in the papular surface, which is effected by desensitization. The authors think that their comparisons of the cellular characteristics and of the sizes of the papules prove that desensitization is accomplished more readily in patients of the third than of the second stage, in the progressive than in the stationary forms, and in the stationary than in the latent forms. They conclude from these observations that the described tests have prognostic value.

Short Wave Treatment of Pleurisy—Schoenemann calls attention to the fact that the cessation of the pneumothorax frequently meets with great difficulties, because the lung shows no tendency to expand again and the patient complains of an unpleasant pressure, which is usually localized in the shoulder. Moreover, the respiration is somewhat difficult. The roentgenogram reveals in these cases frequently a thickened pulmonary pleura, which rigidly covers the lung and gives it a peculiar angular appearance. Refilling of the pneumothorax counteracts the pressure and pains. In such cases, in which the pneumothorax treatment cannot be broken off, the author obtained favorable results with short wave therapy by means of a spark-gap apparatus. Large electrodes are applied anteriorly and posteriorly over the pneumothorax and are left in place for from fifteen to twenty minutes. The patient should feel only a pleasant warmth, not piercing or drawing pains. As a rule the patient requires only a few treatments for soon the lung shows a tendency to expand and the subjective symptoms disappear. The author emphasizes that several factors, namely, the position of the patient, the distance of the electrodes from the body and their size, as well as the duration of the treatment, require careful attention. He recommends short wave therapy for all pleuritic processes, but particularly for the difficulties in cases of pneumothorax.

Necrosis of Pancreas—Sinreich directs attention to cases of pancreatic necrosis the course of which is entirely obscure. The characteristic signs, namely, initial shock excruciating pain and radiation of pains toward the left, are absent. There are some abdominal symptoms with occasional vomiting and with little or no tension in the abdominal walls. There is no discrepancy between pulse and temperature, and even the diastase values are not increased. In spite of this deficiency of symptoms, the necropsy revealed later that a severe pancreatic necrosis existed. In these cases the necrosis had not taken the usual course. The activated pancreatic juice, instead of entering the free abdominal cavity or the omental bursa, had spread into the retroperitoneum—that is, the so-called dorsal course of spreading existed. If the pancreatic secretion enters the free abdominal cavity, the well known fulminant symptoms appear, probably as the result of acute intoxication which in turn is elicited by the autolytic disintegration of the pancreas. The toxic and peritoneal symptoms are milder or absent in retroperitoneal spreading, because of lesser resorption capacity of these tissues. That a subacute ileus may be simulated in the latter cases is probably due to the fact that as the result of the impairment of the nerve centers in the retroperitoneum, the intestinal function becomes disordered. Dorsal spreading of pancreatic necrosis, especially when the process originates on the head or the caudal portion of the pancreas, may also cause destruction of the fatty renal capsule, so that cavities of disintegration may develop in the retroperitoneal region and intestinally infected abscesses may appear. Thus a paraneuritic abscess may result and, if the abscess gravitates downward pelvic or prostatic abscesses may be simulated. On the

other hand, retroperitoneal abscesses involve the danger of later perforation into the free abdominal cavity with the aspects of a fulminant perforation peritonitis. The author calls attention to the frequent concurrence with gallstone disorders and to the postoperative appearance (prostatectomy, operations on varicose veins). In the described cases the direct cause of death was pulmonary embolism and the author points out that thrombosis and embolism are rather frequent in pancreatic necrosis and he suggests that a disturbance in the lipid metabolism might play a part.

Chorionepithelioma in Man—Friedländer and Moses report the history of a man, aged 36, who was hospitalized on account of pulmonary tumor and hemoptysis. The existence of a gynecomastia and the extremely malignant pulmonary metastases made a chorionepithelioma seem likely, the more so since the anamnesis disclosed a temporary enlargement of one of the testes some time previously. The Aschheim-Zondek test was made and, as it was positive, the case was diagnosed as chorionepithelioma. The gynecomastia, the gravidic emesis and the typical gravidic changes in the hypophysis were thought to be the result of the hormone activity of the chorionepithelioma. The patient died and the necropsy disclosed a testicular chorionepithelioma with metastases in the retroperitoneal lymph nodes and in the lungs.

Cholesterolemia in Gallstone Disease—Gukosyan and Antonova studied the blood cholesterol in 171 pregnant but otherwise normal women, of the ages between 18 and 35, in nine women during the second, the seventh and the ninth month of pregnancy, as well as two months after delivery. They draw the following conclusions. The first attacks of gallstone colic coincided with pregnancy in 35 per cent. Hypercholesterolemia is present in the greater portion of the gallstone cases. Blood cholesterol increases with the advance of pregnancy and returns to the normal level two months after the delivery. This increase is the result of functional alteration of liver cells due to initial intoxication of pregnancy. Since the placenta is impermeable to cholesterol its presence in small amounts in the blood of the new-born speaks for possible synthesis of cholesterol in the organism. Cholesterolemia developing in parenchymatous alteration of the liver is caused by the loss on the part of the liver of the capacity for retaining cholesterol. Alterations in the liver observed in gallstone disease are of a primary character and are the cause of hypercholesterolemia in cholecystopathies. Hypercholesterolemia in itself cannot cause gallstone disease.

Coutard's Method of Treatment of Malignant Tumors—Juul shows that opinions differ as to the manner in which Coutard's treatment should be carried out. One of the reasons for this is that Coutard himself never indicated a definite method but always insisted that he did no work according to fixed schematized rules. In general it can be said that Coutard's method of protracted fractional roentgen treatment

employs low intensity and frequent (daily or twice daily) relatively weak irradiations continued over long periods (minimum from three to four weeks). The total dose is high and the individual doses are determined not only according to physical measurements but also on the basis of biologic reactions. Although Coutard emphasized the latter factor, it was lost sight of by many who tried to imitate his method, but the author paid particular attention to this factor. In summarizing the results he obtained, he says that during the period from 1931 to 1934 he employed the protracted fractional roentgen treatment in 121 cases of malignant epithelial tumors of the upper air passages. Thirty eight of these patients, 31 per cent, are still free from symptoms after periods varying from one to five years. During the same period 106 cases of malignant epithelial tumors of the oral cavity were treated. Of these patients thirty-three are apparently well after periods varying from one to five years. Protracted fractional roentgen treatment was employed in seventy-three of the cases, of these, eight are symptom free as a result of the roentgen treatment alone, while ten others became so only after supplementary treatment by radium or electrosurgery. The author briefly considers several other forms of cancer in which the protracted fractional roentgen treatment may be used to advantage. After a detailed account of the manner in which the method is applied at the Radium Center in Copenhagen, the author describes a number of observations made there concerning the reactions produced by the radiation on the tumor, the normal tissues and the organism, and discusses the significance of those reactions. His experience has led him to extend the treatment over a rather long period and to try to keep the reactions within moderate degree. In this way the treatment becomes less trying for the patient without losing any of its effectiveness.

Measurement of Radiation to Which Workers are Exposed—Jacobsen and Ambrosen say that, in the modern roentgen installations with completely inclosed tubes, screening against stray radiation is very effective. Nevertheless there is still a possibility that through carelessness the staff may become exposed to considerable radiation. In the packing of radium applicators the circumstances are similar, but the danger is no doubt greater, since effective screening cannot be carried out. Measurement of the intensity of the radiation in different places combined with an estimate of the duration of the irradiation would give rather uncertain results and the authors think that measurement by means of condenser chambers carried by the persons under observation is much better. This method has the advantage that the intensity is measured right on the person and that the reading can be taken without interfering with the routine work. Moreover, the cost of the chambers is low enough to carry out simultaneously a considerable number of measurements. The author illustrates and describes the condenser chamber that was used for the tests described here. The measurements were carried out over a period of three months. It was found that persons in the x-ray department were exposed to a daily dosage of from 0.02 to 0.03 roentgen. In persons occupied with the packing of radium, the doses were from five to ten times higher.

Gastrogenic Anemias in Dogs—Petri and his co-workers report that the operative removal of the whole stomach with the Brunner gland region in the duodenum in some dogs and of the fundus in others resulted in mainly normochromatic anemias of subacute subchronic character in part fatal in the first group and of more chronic stationary kind in the second group. In two animals in the first group which died after a longer period of observation there were degenerative changes in the gray substance of the spinal medulla. The changes observed after the first named operation, also in general condition and in appearance of the bone marrow, are assumed to depend partly on deficient vitamin metabolism.

THE PROMOTION OF BLINDNESS

A CONSIDERATION OF SOME CONTRIBUTING FACTORS

CHAIRMAN'S ADDRESS

JOHN GREEN M.D.
ST. LOUIS

In the day by day practice of ophthalmology there is much of routine, some of which may be uninteresting. Many of our patients weary us with an endless recital of complaints which arise from some minor surface irritation or error of refraction. Every day or so, however, we are brought up standing face to face with a situation fraught with grave danger to sight. If we give thought to all the attendant circumstances and delve deeply into all the causes that have led to this situation, we shall often become aware that some active factor or factors have operated to promote the impending or accomplished visual catastrophe. It is to a consideration of some of these factors tending to promote blindness that I invite consideration.

What has the ophthalmologist accomplished and what may he legitimately expect to accomplish, in reducing the incidence of blindness? Through personal research but more often in collaboration with workers in biochemistry and other basic medical sciences, he may eventually hope to attain a knowledge of the causes underlying some intra-ocular maladies that today slowly but surely tend to blind their victims. Only when the cause is known can there be intelligent prophylactic or therapeutic attack. Can any one aver that the ophthalmologist has exhausted the possibilities of surgery in preventing blindness or restoring sight? Let him ponder the recent marvelous advance in the operative treatment of retinal detachment, and the remarkable results from the newer methods of keratoplasty. Who knows but that the section papers presented at this meeting may open up new vistas in the surgery of glaucoma?

The young ophthalmologist working in the clinic will inevitably be impressed by the large number of patients who are losing or who have already irrevocably lost their sight from causes that might have been prevented. If he is imbued with humanitarian instincts, he will wonder what agencies are at work to diminish this needless blindness. His investigations will lead him to understand and admire the work of the National Society for the Prevention of Blindness. He will note that the incidence of ophthalmia neonatorum has lessened and that as a result blindness from this

cause has fallen to a new low level. He will note the decrease in accidental blindness from injuries in industry due to the increased use of goggles and other safety devices. He will learn of the decrease in the number of ocular injuries due to unwise celebration of the Fourth of July. He will observe with interest the efforts to prevent blindness from chronic glaucoma by the effective cooperation of the social service department. He will be interested in similar follow-up plans to prevent visual impairment from deep-seated ocular maladies due to tuberculosis, syphilis and focal infections. He will approve the ever widening extension of visual tests for school children in the lower grades and even in the kindergarten. In the initiation and development of all these means for preventing blindness and conserving eyesight he will be able to trace the direct or indirect activities of the National Society for the Prevention of Blindness.

Despite all these efforts of prevention and, indeed, when prevention in one form or another has been used, there still remains an appallingly large number of individuals who, if all the factors tending toward blindness had been combated or eliminated, would not have become blind. It would seem indeed, that the universal utilization of all methods of prevention now known or in the future to be discovered will not suffice to eliminate all unnecessary blindness. We must consider, in addition, all factors which tend actively to promote blindness, for it is only by stopping the "promotion of blindness" as well as by utilizing all measures of prevention that we may finally hope to reduce blindness to an absolute minimum.

Let us consider some of the active factors that promote blindness. I am concerned not only with the major catastrophe of bilateral but with the minor disaster of unilateral loss of sight. While the latter condition does not connote the tragic social and economic consequences implicit in the loss of the sight of both eyes, it does nevertheless present potentialities of subsequent disaster, as every member of this section would undoubtedly bear testimony to.

FACTORS IN CHILDHOOD

Let us begin with the new-born infant. In what percentage of all births is any type of prophylactic used? The careless and ignorant midwife is still practicing. How often actually do these women comply with state laws in the use of preventive drops? How often does the medical practitioner delivering women in remote country homes or in the hovels of the city slums use preventive measures? Does the fear of losing the good will of the parents by the use of eye drops in new-born babies' eyes with its supposed implication of parental immorality operate as a deterrent?

Failure to use prophylactic measures or failure to secure competent ophthalmic care in case ophthalmia develops must surely be regarded as a means of promoting blindness.

The fates seem to have conspired against the unfortunate youngster with cross eyes, or perhaps it should be said that various human agencies militate against the welfare of the child whose eye turns in. In the mind of the average physician, as well as in the minds of parents, the squint is regarded merely as a blemish to be corrected, if inveterate, by surgical means, but to be neglected in its earlier stages in the hope—usually vain—that the youngster "will outgrow it." It is perfectly true that in earliest infancy there is an incoordination of ocular movements, a condition which usually corrects itself. Recalling this transitory infantile incoordination, it is often assumed, erroneously, that an incoordination developing in childhood will also correct itself in time. The advice, therefore, to do nothing until the child is older promotes blindness or near blindness in the squinting eye by allowing the development and perpetuation of a degree of amblyopia that resists all efforts of refraction and training to restore the eye to useful vision. To be of the highest service to the cross-eyed child the ophthalmologist must come into contact with the patient early enough to develop the acuity to the point at which orthoptic training will have a fair chance of developing binocular single vision. The advice which leads to delay in the care of these little patients is reprehensible under any circumstances. It is especially so in large cities, where the opportunities for competent refraction and orthoptic training are available to the most indigent. Until it is borne in on the consciousness of the family physician, parents, nurses, friends and social service workers that the time to begin the care of the cross-eyed child is now, much of the work of orthoptics will prove futile.

Unilateral blindness or near blindness is far more serious than it has actually been regarded. With the pursuit of various forms of strenuous athletic sports during boyhood, youth and young manhood, the possibility of injury to the useful eye is a real hazard. The danger may be less during active adult life unless the individual engages in some industrial pursuit, but it is ever present. It has been my experience that, when in adult life an injury or visually crippling disease occurs to an individual with one amblyopic eye, it is more often than not that the better seeing eye is the victim.

Assuming that the squinting child receives the benefit of early and intelligent ophthalmic care the battle may not yet be won. We still have to cope with the inertia and carelessness of parents who, despite all our efforts, persist in regarding the condition as a minor defect and are all too prone to discontinue bringing the child to the clinic. In the case of private patients whose parents are in the moderate income class, the necessity of frequent visits with the attendant fees may make the undertaking out of the question. Then too, there may arise more serious complications in the household, such as illness or accidents which for the time being will absorb the attention and concentrate the anxieties thus leading to the neglect of the youngster with strabismus. And this neglect is almost certainly translated into a day by day deterioration of vision in the crossing eye.

ECONOMIC CONDITIONS

Let us consider for a moment the influence of the economic depression in promoting blindness. On no class of our people has the prevalent existence of poverty, the superpoverty of recent years, wrought more havoc than on the dwellers in the hills and mountainous regions of Kentucky, Tennessee, Missouri and Arkansas. Even under the best economic conditions these poor whites live neglected lives in one or two room shanties with never enough food to maintain the nutrition of the usually very large families. Under the best of conditions they glean a mere pittance from tilling the soil. As if conditions of life and livelihood were not bad enough, they have become afflicted, whole families of them, with that terrible scourge trachoma. Indeed, in their mountain cabins these people endure their afflictions resignedly, until loss of vision rather than pain, to which they seem to have become accustomed, forces some attempt at getting medical aid.

In Missouri and elsewhere, physicians of the United States Public Health Service have performed valiant service in ferreting out and caring for many of these people. The work, however, is truly discouraging, for the capacity of the trachoma hospitals is limited, hence only the worst cases can be accepted for hospitalization. Those who come are helped but before the disease can be arrested they are forced, for economic reasons or to make room for still more urgent cases to leave the hospital and return to their homes. As they are not cured a revisit or several revisits to the hospital are inevitable.

EDUCATION

All will recall how, at the turn of the century, the teaching of medicine in many small unendowed medical schools in this country was subjected to a searching survey by the American Medical Association. All are familiar with the devastating effect of these investigations on many of the weak sisters. The more hopeless of these schools found the pressure more than they could stand and so crumpled up and died. Others found that their continued existence implied a transfusion of blood from a stronger institution. Thus by slow degrees, the standards of medical education were elevated. The output of doctors decreased but the quality improved.

While in general there was marked betterment in the situation, the opportunities for the training of men desiring to specialize in ophthalmology left much to be desired. Sometimes the middle-aged practitioner, yearning for a less arduous and physically harassing existence than was inherent in general practice, sought to equip himself in as brief a time as possible as a specialist in ophthalmology and otolaryngology. There was a demand for the "get equipped quick" institution and that demand was supplied. These "specialist mills" turned out a product equipped with confidence (if nothing else) to prey—and I use the word advisedly—on the innocent communities wherein they elected to practice. It was a situation to make the judicious grieve, but some of the judicious, not content with grieving, set about to devise a means of testing the fitness of doctors who offered themselves as practitioners of ophthalmology. Thus was conceived and born in the minds of three of our most distinguished and far-seeing colleagues, Drs. Edward Jackson, Walter B. Lancaster and the late William H. Wilder, the idea of an American Board of Ophthalmology which should be fully representative of ophthalmology in the United

States and should have the power to issue certificates to those who proved by examination their fitness to practice our specialty. All honor to these pioneers who builded better than they knew. To these men and to others associated with them is due the conception of a truly great idea, an idea that has gripped the imagination of the leading men in all the different specialties. Today there are twelve similar boards organized or in process of organization in the twelve major specialties.

It is not pleasant to speak of the part played by poorly trained ophthalmologists in the promotion of blindness. A few such men are still in practice, but, happily, their numbers are diminishing year by year, largely as the result of the efforts of our board and the ever increasing opportunities for systematic training. Through ignorance due to lack of adequate training they are actually promoting blindness by wrong advice, failure to make correct diagnoses in ocular maladies tending to blindness, and clumsiness in operative work. Perhaps this incompetence is displayed most conspicuously in the management of patients with chronic glaucoma. In all fairness it should be stated that some of these practitioners may in reality recognize that they are dealing with glaucoma but, having convinced themselves of the futility of any measure other than the operative one to cope with this disease and not having the temerity to undertake any operation, have allowed such patients to drift into blindness. All will agree that such conduct is reprehensible and indefensible, for if there is one thing that is paramount it is the interest of the patient. Neither ignorance nor cowardice can exculpate an ophthalmologist who withholds from a patient the advice to seek more skilled care when he feels incapable of rendering such care.

Another active agent in the promotion of blindness from glaucoma is the attitude of the patient himself. There seems to be something in the insidious, slow, nearly painless progress of the disease, at first essentially confined to one eye, that numbs the initiative of the patient, rendering him incooperative with his adviser, and perfectly willing to let matters drift. This is especially characteristic of the clinic patient who interprets the cautious words of explanation and perhaps evasive manner of the ophthalmologist as an estimate of the hopelessness of his case, so he in turn promotes his own blindness by discontinuing visits or treatment, or both. It is this attitude on the part of the patient which has impelled most clinicians to insist on early operation, as experience has shown that not one in twenty of these patients will follow instructions and keep up for months and years the needed medical treatment.

THE ROLE OF THE OPTOMETRIST IN THE PROMOTION OF BLINDNESS

Here we come to a difficult and perplexing question. Unfortunately the legalizing of optometry and the licensing of its practitioners has developed a business widely accepted by the people as a profession, a conception that the optometrists themselves have done their utmost to promote and perpetuate. It is this conception of optometry as a profession with its offices, testing paraphernalia, diplomas, state certificates of licensure, and the use of the title "doctor" which so bemuddles the client. The acceptance by the vast majority of Americans of the optometrist as adviser in every case of failing vision is a sad commentary on the gullibility of our people as well as a tribute to the effectiveness of optometric advertising.

Let us freely grant that there are optometrists who are honest and, within the limits of their training and methods of examination imposed by law, reasonably competent. Some may have attained a modicum of diagnostic skill enabling them to hazard, at least, a shrewd guess as to the existence of a pathologic state in the eye. But unfortunately optometrists of this type do not predominate. They are powerless to prevent the entrance into the business of countless men whose sole purpose is to sell as many and as expensive eyeglasses and spectacles as possible.

NEOPLASMS AND INFECTIONS

Another factor in promoting blindness is the failure on the part of some physicians to recognize the existence of intracranial neoplasms before irrevocable damage to sight has occurred as a result of the development and long existence of papilledema.

Why, one may ask, in the presence of all the signs of brain tumor does the attending physician so often wait until the patient has lost most of his vision before counseling consultation with the ophthalmologist or neurologic surgeon? Perhaps it is too much to expect of the physician that he make a precise ophthalmoscopic diagnosis, but at least he should be sufficiently skilled to recognize the difference between a normal and an abnormal optic nerve head. One of the major sorrows of the neurologic surgeon is that, no matter how skilfully and completely he may remove a brain tumor, he is often powerless to restore vision, to paraphrase the old saying, "The operation was successful but the patient was blind." Even when the tumor cannot be localized or, if localized, cannot from its nature be totally eradicated, a decompression will usually promptly bring about a subsidence of the papilledema, and in cases in which optic atrophy has not begun, vision will be preserved to the end of the patient's life.

I have been impressed with the tendency of some physicians, in the presence of a brain tumor syndrome, to "try out" antisyphilitic treatment even in the absence of serologic or other evidence of syphilis. This period of trial may very well be that precious time when brain surgery would have saved sight. The prolongation of such unnecessary and contraindicated treatment will often bring the unfortunate victim to the ophthalmologist and neurologic surgeon too late to prevent total loss of vision.

In the presence of certain infiltrating diseases of the cornea, chronic iritis, cyclitis and uveitis, it is my impression that in the search for focal infections and syphilis the possibility that tuberculosis is the actual causative factor is frequently forgotten. Curiously enough, the victims of ocular tuberculosis are often individuals of robust appearance. They may have acquired a low grade pulmonary tuberculosis in childhood or early adult life and on account of native resistance have experienced a spontaneous arrest of the pulmonary process. No subsequent breakdown having occurred, the very late appearance of ocular tuberculosis takes the form of a clinical surprise. It is granted that the diagnosis of many of these cases is not easy and sometimes has to be arrived at by a process of elimination. If, however, the eye is actually a tuberculous one the elimination of foci of infection and the giving of antisyphilitic remedies may promote blindness or result in seriously impaired vision before the true etiology is discovered and appropriate treatment is instituted.

CONCLUSION

I have discussed a few of the factors that tend to promote blindness. Others, perhaps equally important, have not been touched on. If we ophthalmologists do not take cognizance of and valiantly strive to combat all factors which, either directly or indirectly, tend to promote blindness, we are not doing our share in the world-wide effort to reduce this affliction to an absolute minimum.

3720 Washington Boulevard

THE CHICAGO CITY-WIDE PLAN FOR THE CARE OF PREMATURE INFANTS

JULIUS H. HESS, MD
CHICAGO

The plan of procedure that I shall discuss was started in Chicago in March 1935, and an outline of the plan was presented at a round table discussion on prematurity at the meeting of the American Academy of Pediatrics, June 7, 1935.

The Premature Station at Sarah Morris Hospital, established in 1922, was the first of its kind in Chicago that was willing to receive premature infants born in other hospitals and in homes. The demand for such a station is evident, as shown by the gradual increase in the number of patients admitted, from nineteen in the first year of operation to 272 in 1935. As early as 1930 the station became overtaxed, and provision was made for the opening of a station at Cook County Hospital to care for infants born in the hospital and of patients received from other sources. The Cook County Hospital station for premature infants admitted 253 infants in 1934 and 286 in 1935. At the present time at least two other hospitals have plans well under way to open such special wards. At Cook County Hospital all patients are treated free of charge, and at Sarah Morris Hospital approximately 75 per cent receive free or very low cost service.

Infant death rates in many large cities have remained at much the same percentages with relation to the total of births during the five years preceding 1935. In Chicago the deaths per thousand live births (under 1 year of age) were 1930, 53.4, 1931, 56.4, 1932, 48.2, 1933, 48.8, 1934, 47.7, 1935, 40.1. A study of the reported causes of death led to the belief that efforts to reduce the death rates further must be directed toward conditions associated particularly with early infancy, such as maternal illness, birth injuries, premature birth and congenital malformations.

In Chicago a survey carried out by the United States Bureau of the Census during 1935 showed that there was 99.5 per cent registration of births. The infant death rate of 40.1 for 1935 may therefore be considered as a true figure of what is occurring in Chicago. It should also be noted that the stillbirth rate has been steadily declining during the same period. The smaller number of infant deaths recorded should therefore exclude the thought that there might be a tendency to classify as stillbirths infants born alive but dying soon after birth.

In attempting to clarify statistics covering survival and deaths due to prematurity from various cities and

clinics, it should be borne in mind that those from general and lying-in hospitals whose nurseries receive only infants born within their own institutions must of necessity be given a different interpretation from premature infant stations in children's hospitals, such as Cook County, Sarah Morris and Boston Children's, which receive infants from all sources. The municipal statistics cover all infants born in the city, just as those of the general hospital cover all infants born within its wards, while stations in children's hospitals cover only such infants as are received from various sources. It is to be remembered that many of the latter are received in poor condition, as the result of delay and exposure during transportation to the station. For this reason most special stations classify their deaths into time periods of twenty-four hours, forty-eight hours, ninety-six hours or later. In many instances, at least a temporary delay in transportation of the infants is justifiable, owing to the dangers of undue handling, if the infant can be properly protected against refrigeration.

With all these facts in mind and believing that deaths from prematurity might be lowered by well organized effort, Dr. Herman N. Bundesen, president of the Board of Health of Chicago, initiated the Chicago city-wide plan for the reduction of deaths associated with and due to prematurity.

Prematurity was stated as being the cause of death in 749 infants during 1934. During 1935, of 1,361 infants who died under 30 days of age, 795, or 58.4 per cent, were reported as being premature. A reduction in morbidity and mortality rates among prematurely born infants seemingly offered a promising field for lowering the death rate among new-born infants. It was felt that, if the same principles established in con-

TABLE 1—City of Chicago Vital Statistics 1930-1935

| Year | Total Live Births | Stillbirths | | Total Deaths Under 1 Year of Age | | Deaths Under 1 Month | | Deaths per 1,000 Total Population |
|------|-------------------|-------------|-------|----------------------------------|------|----------------------|-------|-----------------------------------|
| | | Number | Rate* | Number | Rate | Number | Rate* | |
| 1930 | 58,083 | 2,072 | 3.7 | 3,102 | 53.4 | 1,789 | 30.8 | 1.2 |
| 1931 | 52,993 | 1,006 | 3.0 | 2,087 | 50.4 | 1,662 | 31.4 | 1.3 |
| 1932 | 49,258 | 1,335 | 3.1 | 2,404 | 48.8 | 1,461 | 29.8 | 1.0 |
| 1933 | 46,655 | 1,405 | 3.0 | 2,278 | 48.8 | 1,454 | 31.0 | 1.0 |
| 1934 | 47,055 | 1,399 | 2.9 | 2,289 | 47.7 | 1,481 | 30.0 | 1.1 |
| 1935 | 49,432 | 1,328 | 2.6 | 1,983 | 40.1 | 1,361 | 27.5 | 1.2 |

* Per thousand live births.

ducting the premature station at Sarah Morris Hospital could be applied in a Chicago-wide program, many premature infants now lost might be saved.

The Sarah Morris station offers

- 1 Ambulance service by the hospital
- 2 Premature ward care with special equipment for oxygen therapy and other types of emergency therapy
- 3 Nursing service by a trained personnel
- 4 Breast milk obtained from wetnurses and visiting mothers
- 5 Field nursing service for instruction of the mothers, special attention being given to the promotion of breast milk secretion. Breast milk in the home reduces the number of hospital days.
- 6 A supply of a simple type of heated bed lent for the use of graduates in the home. This is of special value in reducing the number of return cases due to acute illnesses after discharge.
- 7 An outpatient clinic maintained for instruction of mothers and the care and supervision of graduates not having private physicians.

Therefore, the program here presented, which is an attempt to apply institutional procedures already found

successful, expanded to meet the demands of a large metropolitan community, was adopted by the Board of Health

It became apparent that it would be necessary to determine through a survey exactly what facilities the hospitals of Chicago afforded for the proper care of the premature infant. This seemed the more important in that an analysis of the death certificates of the year 1934 showed that the death rate of premature infants in institutions properly equipped for their care was much less than the rate in institutions in which such care was not available.

Before the survey was made, with the advice and help of the physicians who had specialized in the care of the premature infant, a set of minimum requirements for hospital care of premature infants was drawn up by the Board of Health. Not only did these requirements serve as a yardstick for the survey, but a copy was sent to every hospital, to be posted in a conspicuous place in the nursery.

MINIMUM REQUIREMENTS FOR HOSPITAL CARE OF PREMATURE BABIES

Accommodations—It is recommended that, if possible, a separate room be set aside for the care of premature infants. Otherwise they may be cared for in the nursery.

Every hospital should have some type of heated bed in the nursery or premature room.

Oxygen should be used whenever indicated and a supply for use in emergencies with necessary equipment should be kept in the room occupied by the premature infants.

Provision for the prompt transfer of the premature infant from the delivery room to the nursery should be made, so that there is no exposure of the infant to chilling.

Equipment for Nursing Care—Individual equipment should be provided for the premature infant, especially a bath basin and a thermometer.

If the premature infant is cared for in the nursery with the other infants, it is advisable to keep the feeding equipment for stored breast milk (droppers, nipples, etc.) in a separate place from that of the other infants.

Every baby should have his own catheter.

There should be running water in the room or nursery, or it should be easily accessible.

Cans or diaper bags should be available for soiled linen and diapers. If possible a warmer for clothing and diapers should be available.

The room or nursery should have a "high and low" thermometer (to show the temperature variation within twenty-four hours) and a hygrometer.

A heated bath table is desirable.

Nursing Care—The nursing care of the premature infant should be supervised by a graduate nurse who has had special training in the care of the premature infant. The Board of Health on request will send a nurse to give instructions in the management of premature infants. A twenty-four hour nursing service should be provided. Nurses and attendants with respiratory or intestinal infections should be excluded from the nursery.

A minimum amount of handling is advised for premature infants. There are few nursing procedures with the exception of weighing and bathing which necessitate removal of the infant from the heated bed.

Wool is the preferable material for the clothing of the premature, and the infant must at all times be guarded against exposure to cold during dressing.

It is recommended that physicians, nurses and all others entering the room in which the premature babies are cared for should wear a clean gown and face mask.

The room temperature should be 78-80 F.

Proper nursing hygiene, especially washing of hands is essential to prevent infections. Infected cases should be isolated.

It is advised that every premature baby receive breast milk. If the milk is obtained outside the hospital it should be boiled in the hospital for from one to two minutes before it is used.

The Board of Health, on request, will furnish information as to where breast milk for premature infants can be obtained.

Nurses caring for premature infants should be familiar with the methods of treating cyanosis in such infants.

It is strongly recommended that the obstetrics department in hospitals where it is customary to place the responsibility for care of the new-born on the pediatric department notify the pediatric department in advance of every delivery in which the uterogestation is expected to be less than term and more than four months. It is also suggested that the pediatric department respond to such notification by assigning to the delivery room an attendant especially trained in the early care of premature infants. Such attendant should be a member of the hospital personnel and constantly on call. The premature infant should always be placed under the care of the premature department immediately after birth.

Discharging Infants—No premature infant who will not be under the care of a private physician at home should be discharged from a hospital without first notifying the Board of Health. If parents are not financially able to have a private

physician for the infant after its discharge from the hospital, the Board of Health will assign a nurse to the home to give instructions to the mother and to render the necessary follow-up service.

A graduate nurse, trained at the Sarah Morris Hospital Premature Station and experienced in the care of the premature infant, was assigned to make such a survey.

After the completion of the survey a scoring sheet was drawn up, and each hospital was rated on the basis of equipment for caring for the premature, as compared with the minimum requirements (table 2).

All hospitals that did not meet these minimum requirements were sent a detailed statement of the points in which they fell short. A follow-up investigation for assistance to the hospitals was also made by a physician experienced in the care of premature infants.

An interesting point brought out by the survey was that, while equipment is important, elaborate equipment does not necessarily mean efficient and effective service.

More important is an intelligent understanding of the care of the premature infant, especially in respect to such points as maintaining proper temperature, the treatment of cyanosis and knowledge of feeding, together with an enthusiastic staff

CARE OF PREMATURE INFANTS

For a better understanding of the causes of death of premature infants, a plan for the investigation of the death of every premature infant in the city after Jan. 1, 1935, was instituted

It immediately became apparent that in attacking the problem of prematurity, just as in an epidemic the number of cases of contagion must be known, it would be essential to have early reports of premature births. Therefore on March 5 the Board of Health passed a regulation making premature births immediately reportable by telephone, followed by written confirmation within twenty-four hours. Notification of this ruling was sent to all physicians, midwives and hospitals.

The public health nurse has demonstrated her value in so many life-saving activities that it was felt that she would be an essential factor in the carrying out of this program. However, if she was to render effective service, it would be necessary for her to be well trained in a rather highly specialized and, as a public health activity, new and untried phase of nursing.

Such a program of training was started at once. The nurses of the staff of the Board of Health were assigned in small groups at a time to Sarah Morris Hospital and Cook County Children's Hospital, which were conducting premature stations. As soon as three nurses had finished the training, the city was divided into three districts, and one of these nurses was assigned to each district. Each nurse is responsible for the premature infants in her district. As other nurses finished their training and as the work grew, additional nurses were assigned to the district as needed.

Twenty-three nurses have received instruction in the care of premature infants at the Sarah Morris Hospital. The course of instruction was for three weeks. One hundred and forty-two nurses received instruction at the Cook County Hospital, each for a period of six days. All of these 165 nurses were instructed in the method of hand expression of breast milk so that they in turn would be able to teach the mothers of premature infants to maintain the supply of breast milk.

The district nurse is responsible for every premature baby in that district whether the infant is at home or in a hospital. If the baby is in a hospital, the nurse maintains contact with the hospital so that she will know when the baby is to be discharged. A baby in a hospital may reside in a different district. Therefore the nurse in the district where the baby is hospitalized notifies the nurse in the district where the baby resides when the baby is to be discharged from the hospital. In all hospital cases the nurse goes to the home shortly after the birth and before the baby is discharged, if it is a hospital case to see that the necessary preparations are made for the proper care of the baby.

It is important to understand the relationship of the nurse to the private physician in this program. If an infant is under the care of a private physician the nurse checks with him before taking active charge of the case. The services of the nurse are at the disposal of the physician. At his request she goes into the home to help in such matters as maintaining the supply of

breast milk, teaching the mother manual expression and, if the circumstances of the family so indicate, assisting with the nursing care of the baby.

It was realized that there will always be infants who cannot have breast milk from their own mothers and that some of these will be prevented from having it from commercial supplies because of economic reasons. To provide for the latter group of infants a mother's breast milk station has been established by the city of Chicago. This brings the number of breast milk stations in the city to four, there are three in hospitals (two in the hospitals that maintain the premature stations previously mentioned) and a commercial station in another hospital. The first two hospital stations attempt to care primarily for their own needs, having only a limited amount for sale. It has been agreed with the commercial station that it will take any case in which there is ability to pay something, though below the price ordinarily charged. The board of health station is caring for the wholly free cases and has collected 46,765 ounces of breast milk during its first year of operation. It furnished milk for 144 babies and the average length of time that this group of babies received milk was 20 2/3 days, with an average of 309 ounces per baby. The approximate cost per ounce was 9 1/3 cents and the average cost per baby was \$28.89. The station at Cook County Hospital collected 76,960 ounces of breast milk during 1935.

If a feeding problem or illness occurs in the case of a premature infant whose parents are unable to provide a private physician, a physician experienced in the care of young infants is sent to make a special call.

The city also purchased a number of heated beds for lending to those institutions and homes in which other facilities are not available for maintaining the body temperature of premature babies. An incubator ambulance was also provided to transport these infants without charge from homes and institutions when proper facilities were not available. The service is also available to infants when they leave the hospital.

There have been established three conference clinics for premature infants not cared for by private physicians who have graduated from hospital premature stations and those born and cared for in their own homes—one each on the north, west and south sides of the city. The nurse in charge of that particular district will also be in charge of the conference on prematurity.

All cases from the Cook County Hospital needing antisyphilitic care are reported to the board of health and then are assigned to the field nurses for special follow up. This is to insure as nearly as possible the return of these women to the clinics for antisyphilitic treatment.

An illustrated pamphlet outlining the care of premature babies is also available.

A study of the death certificates also revealed that many of the premature infants died within several hours of birth. It was thought that possibly in some cases these deaths were the result of improper methods of resuscitation. In order to determine what the medical profession considered acceptable methods, a questionnaire was sent to a larger group of physicians practicing obstetrics. The replies to these questionnaires were tabulated. Some methods still in use were found to be in disrepute, while others were highly advocated. The conclusions were that postural drainage, pharyngeal and in exceptional cases, tracheal aspiration, oxy-

gen, oxygen and carbon dioxide mixtures, warm baths, and mild forms of artificial respiration were recommended. All strenuous handling that might traumatize the infant was condemned.

Many of the infants of mothers who received morphine, scopolamine and the various barbituric acid compounds during labor were born with the full effect of the medication. In some, respiration was established with great difficulty. Others died without emerging from their narcotized and asphyxiated state.

Of the 795 premature babies who died, 85, or 10.7 per cent, died within an hour of birth, and 554, or 69.7 per cent died within twenty-four hours.

Pathologic conditions in the mother which had a more or less direct influence on premature delivery were recorded in 355 histories or 44.6 per cent of all cases. Undoubtedly there are others not recorded in the obstetric records. The most frequent were toxemia, external injury fifty-four, abruptio placentae twenty-one, placenta praevia thirty-eight, syphilis twenty-five, other infections thirty, and nonobstetric surgery twenty-five.

For 450 infants, prematurity was the only assigned cause of death. In the remaining 345 various contributing causes were recorded, the more frequent being atelectasis 176, cerebral hemorrhage fifty-eight, malformations sixty-one. Of the latter, cardiac and cephalic malformations were the most frequent. Autopsy was performed on 251 of the infants.

Of the 795 premature infants who died under 1 month of age, 74.8 per cent were born in Chicago hospitals, 24.4 per cent were born at home, and 0.8 per cent were born outside the city or en route to a hospital, or the place of birth was not known. Five hundred and seventy-six died in the same hospital in which they were born, 105 died at home, five died en route to a hospital, and eighty-seven were born at home and died in a hospital.

TABLE 3—Data on Vitality of Premature Infants Graduated from Sarah Morris Hospital, 1922-1935

| Birth Weight In Gm | Total Admis- sions | Surviving | | | Gradu- ated | Per Cent | Per Cent Graduated of Infants Surviving First 48 Hours |
|-----------------------|--------------------------|----------------------|----------------------|----------------------|----------------|-------------|---|
| | | First 24 Hours | First 48 Hours | First 96 Hours | | | |
| Under 1,000 | 106 | 45 | 32 | 28 | 16 | 15.1 | 50.0 |
| 1,000-1,500 | 417 | 23 | 230 | 267 | 187 | 45.1 | 72.2 |
| 1,500-2,000 | 67 | 697 | 689 | 685 | 566 | 70.4 | 87.0 |
| 2,000-2,500 | 684 | 669 | 662 | 661 | 600 | 87.4 | 90.6 |
| 2,500-3,000 | 93 | 91 | 91 | 91 | 83 | 91.2 | 91.2 |
| Over 3,000 | 5 | 5 | 5 | 5 | 3 | 60.0 | 60.0 |
| Unknown | 50 | 47 | 41 | 41 | 30 | 60.0 | 73.1 |
| Totals | 2,122 | 1,837 | 1,779 | 1,768 | 1,505 | 70.9 | 84.6 |

In 1935, 1,862 infants out of 49,425 live births were classified as being prematurely born. This is a rate of 37.7 premature births per thousand live births. Seven hundred and ninety-five premature infants died in homes and various hospitals from all causes, with a mortality rate of 42.6 per cent. The average mortality rate of the Sarah Morris Hospital station of 24.06 per cent during the past five years and the marked decrease in the deaths among premature infants at Cook County Hospital from 49.2 in 1932, 37.3 in 1933, 34.2 in 1934, and 24.8 in 1935 demonstrate the possibilities for the saving of these lives.

Of greatest importance is adequate antepartum care of the mother as evidenced by the number of cases of

pelvic deformity, placenta praevia, toxemia, cardiac conditions and syphilis recorded as contributing to premature delivery. Serologic reactions were obtained on 413 mothers of 1,862 premature infants reported in Chicago during 1935. Of these twenty-three, or 5.6 per cent, were positive. At the Sarah Morris Hospital 8.1 per cent of all admissions over a period of twelve years were diagnosed as being born to syphilitic parents, of these, 31 per cent died in the station.

SUMMARY

1 While the results of one year of organized effort does not offer material for drawing conclusions as to the result in the lowering of deaths due to prematurity, a drop in deaths of all infants born in this metropolitan area from 47.7 in 1934 to 40.1 in 1935 per thousand

TABLE 4—Cook County Hospital

| | 1932 | 1933 | 1934 | 1935 |
|--------------------------|------|------|------|------|
| Premature admitted | 128 | 233 | 253 | 294 |
| Mortality rate | 49.2 | 37.3 | 34.2 | 24.8 |
| Excluding 24 hour deaths | 30.4 | 27.0 | 21.5 | 9.5 |

live births appears significant in that the program initiated may have borne results in lowering the death rate among all new-born infants.

2 During 1935 it was required that all infants that breathed be reported as live births, and this in all probability was a factor in the increased number of premature births reported over 1934 and therefore makes it impossible to draw comparative conclusions covering these two years. Attention is called to the decreased number of stillbirths reported 1,328 in 1935 as against 1,399 in 1934.

3 The decreased mortality among Cook County Hospital and Sarah Morris Hospital premature infants during the past five years is evidence of the results to be expected from a well organized program.

4 Of special importance are antepartum care of the mother and avoidance of extreme narcosis during labor, also traumatism in attempts at resuscitation and chilling of the infant at all times.

5 Breast milk, intelligent nursing care and proper instruction to the mother in the care of her breasts and her baby all tend to a lowered mortality.

6 Follow-up visits lower not only mortality but, equally important, morbidity.

104 South Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. MAURICE L. BLATT, Chicago. As a result of the untiring effort of Dr. Hess the premature infant born in Chicago finds a medical and nursing group specially trained and prepared to administer to its needs. A consciousness of the fragility of the life of the premature infant lessens its hazards. The widespread recognition of any continuous threat to human life challenges medical combat. We have accepted that challenge under Dr. Hess's leadership. If our co-workers, the obstetricians, will give us fewer infants under 1,250 Gm at birth, we will improve the vitality statistics of the past. I believe that in the near future the obstetricians will gain control of some of the other causes of premature birth just as they have reduced the incidents ascribed to congenital syphilis. The Premature Station at Cook County Hospital is an integral part of the city-wide plan. Its primary function is the care of the infant born in Cook County. It assumed as an additional function the teaching of the care of the premature to 143 public

health nurses of Chicago. These nurses were taken into our department in groups of six for half days on two successive weeks. They were familiarized with the care of premature infants by lecture and demonstration, and during their last periods were allowed to work in the wards with our infants. Needless to say, their work in the wards was preceded by throat cultures, Dick tests and Schick tests. All with any suspicion of infection were kept from this intimate contact in the ward until such infection had passed. While it was considered that using such infants for teaching purposes was a dangerous procedure, we had confidence in our technic. During the several months of such use no infection occurred in my ward. The nursing procedures in Cook County Hospital are based on aseptic nursing technic, the application of external heat, the feeding of adequate amounts of fluid, the use of breast milk from carefully selected wetnurses, and the establishment of a fixed personnel for the supervision and care of these premature infants. Our observation confirms that of many previous workers in that it has been found that manually expressed breast milk, aseptically collected and immediately iced, is the most satisfactory food for these infants. The accompanying table demonstrates the efficiency of the organization and procedures during 1935.

Data of Mortality During 1935

| Admission Weight Gm | Total Admissions | Surviving | | | Graduated | | Graduated Infants Surviving per Cent | |

DR WILLIAM J. ORR, Buffalo. After listening to the splendid presentation of Drs. Hess and Blatt, I have little to offer save words of congratulation for their success. The sustaining of life in a premature infant has always presented a challenge to the medical profession. That challenge hasn't been met until recently, and then only in isolated instances. The work of Dr. Hess is noteworthy and he is to be congratulated on his achievement. The cooperation of obstetricians, physicians, pediatricians, public health authorities and hospitals is needed if the premature death rate is to be lowered. An educational program, similar to that which Dr. Hess, Dr. Blatt and others are carrying on in their communities, should become nationwide in its scope if we are going to be able to show that the problem is not a hopeless one and that the small lives are worth salvaging. Perhaps our failures in the past have been because the pediatrician has been forced to extend his efforts in an attempt to repair the damage already done before the premature infant became his charge. In the wards for premature infants at the Children's Hospital of Buffalo, most of the children admitted were in a desperate condition. I do not present these figures as a boast of achievement but rather as an illustration of the gravity of the problem that confronts the hospitals throughout the country. Over a period of three years we had 108 children admitted to our premature ward. Of that number seventy-four or 69 per cent died. One hundred weighed less than 2 000 Gm, fifty-six infants or about 56 per cent weighed less than 1 500 Gm, forty-one or 38 per cent weighed less than 1 250 Gm. Only 31 per cent of the total number admitted reached the hospital before they were 24 hours old, and in only eight instances were we so fortunate as to receive these patients before they were 12 hours old. In the seventy-four deaths thirty-six occurred within twenty-four hours following admission. Unquestionably with timely intervention and with cooperation and team play such as has been organized in Chicago these mortality figures could have been reduced considerably.

THE TREATMENT OF DELIRIUM TREMENS

WILLIAM B. CLINE JR., MD

AND

JULES V. COLEMAN, MD

VALHALLA, N. Y.

It is our purpose in this paper to present certain data on the history, etiology and pathology of delirium tremens and to call attention to a method of treatment which in our hands has given good results. In any discussion of delirium tremens it would hardly be possible to disregard entirely the larger problem of chronic alcoholism, of which delirium tremens is only a special phase or, one might say, a dramatic incident. However, if we refer at times to the problem of chronic alcoholism, it will not be in the attempt to contribute to its understanding but only better to clarify the various aspects of delirium tremens.

By way of introduction, it would seem helpful to explain just what we mean by the term chronic alcoholism, that is, at just what point in the scale does the user of alcohol cease to be a normal or heavy drinker and become a chronic alcoholic? Very few writers on the subject attempt to make such a differentiation, but Peabody¹ has adopted a criterion that would appear to be quite useful. He considers that normal drinkers are those to whom a night's sleep represents the end of an alcoholic occasion, that chronic alcoholics are those to whom a night's sleep is only an unusually long period of abstinence. In other words, chronic alcoholism properly belongs in the group of habituations.

It is only among the group of habitually severe and consistent users of alcohol, then, that delirium tremens develops. Many of those who come to us for treatment of delirium tremens are so-called spree drinkers, but in each case the spree has been an uninterrupted period of drinking day and night for weeks or months, or it may have been a period of unusually heavy drinking in one accustomed to have his daily pint of whisky over a period of years. Occasionally, a severe infection or injury in a steady drinker appears to have precipitated the illness. There would seem to be little relationship between the amount of alcohol consumed and the development of delirium tremens, beyond the amount of drinking necessary to qualify as a chronic alcoholic.

A word of introduction might also be said to draw attention to the importance of alcoholism and delirium tremens as a medical problem. Nicoll and Bellows² made a confidential survey of deaths in Westchester County in an effort to learn just how many were attributed wholly or in part to alcohol and syphilis. Their study revealed the surprising fact that alcohol contributed to or directly caused 7.3 per cent of deaths in males and 1.4 per cent of deaths in females during the years 1931-1933. In this connection Hunt³ says:

From almost every standpoint ethyl alcohol must be regarded as the most important poison with which medical men and jurists have to deal, no other poison causes so many deaths, or leads to or intensifies so many diseases, both physical and mental, as does alcohol.

From the Psychiatric Institute, Grasslands Hospital.

in the various forms in which it is taken." Thus it would seem that alcoholism is a real medical problem and not merely a social problem, as many would appear to believe. It is surprising, then, that standard medical textbooks and teaching concern themselves so little with therapy in alcoholic conditions, especially in view of the fact that a considerable body of literature dealing with this subject has accumulated during the past twenty-five years.

HISTORY

Delirium tremens was first accurately described by Sutton⁴ of Greenwich, England, in 1813. He observed it in sailors who indulged to excess in alcohol during their time ashore. Ware⁵ of Boston gave an excellent description in 1831 of the clinical manifestations in this condition. He stated that in his hands expectant and supportive treatment had proved much more effective than the drastic purges and venesection then used in this and most other medical conditions. Since the time of Sutton and Ware there have been very few improvements on the "expectant and supportive" therapy as far as the accepted general practice is concerned. In other words, during the last hundred years little or no progress has been made in the generally accepted treatment of delirium tremens.

ETIOLOGY

Beyond the fact that, as already stated, delirium tremens occurs as an incident in chronic alcoholism and that it often follows on injuries, operations and acute inflammatory disease, very little is known of the actual etiologic factors. Fractures are frequently mentioned as of etiologic importance, but it is well to remember that such injuries may have occurred in the prodromal period and are in such cases more apt to be a result than a cause of the illness. Pneumonia has been cited as the most commonly associated inflammatory disease, and the possibility of a causal relationship has been suggested.⁶ We have almost invariably observed that the delirium developed when the drinker's food intake was limited almost entirely to alcohol. This would seem to indicate that a nutritional factor, such as vitamin deficiency, might be responsible for the delirium. It has been demonstrated⁷ that polyneuritis in alcoholic addicts is due to a deficiency of vitamin B₁ in the diet and that alcohol as such does not have a direct neurotoxic effect. However, Jolliffe, Colbert and Joffe⁸ have found that there is no very clear correlation between the degree of vitamin B₁ deficiency and the presence or absence of involvement of the central nervous system. Further vitamin studies in the alcoholic psychoses would undoubtedly be of great value.

Two other hypotheses have been prominent in the discussions of etiology in delirium tremens. The theory of secondary or intermediate toxins was in vogue at the turn of the century. According to this theory, the delirium was directly caused by the action on the brain of a secondary or intermediate toxin arising in the gastro-intestinal tract,⁹ in the kidneys,¹⁰ or in the central nervous system.¹¹ Steinbach¹² also thought that a

toxic agent was present in the spinal fluid but did not attempt to demonstrate it.

The second and perhaps the most widely accepted theory in the past and at the present time is that delirium tremens results directly from the sudden deprivation of alcohol in the heavy drinker, the so-called abstinence delirium. Many capable clinicians still hold steadfastly to this traditional idea, which in our opinion is entirely erroneous. Ashworth,¹³ for example, states that he has never observed delirium tremens except in cases in which the alcohol had been abruptly withdrawn, and Williams¹⁴ and Lambert¹⁴ maintain that gradual withdrawal of alcohol is desirable or necessary if delirium is to be avoided in the treatment of the chronic alcoholic addict. Towns¹⁵ likewise holds that delirium tremens develops only when alcohol has been suddenly withdrawn. Osler¹⁶ and Meyer¹⁷ have also contributed to the survival of the abstinence theory.

On the other hand, Holitscher¹⁸ states that abstinence delirium, if it occurs at all, is extremely rare, and Bleuler¹⁹ says that in his experience in hardly one case in a thousand did delirium develop after abrupt withdrawal of alcohol, except when a careful history and examination at the time of withdrawal revealed prior evidence of early or impending delirium. This he emphasized with the terse remark "The omission of alcohol kills nobody. It is only the use of it that does."

In this connection Jelliffe and White²⁰ quote English prison statistics to the effect that of 63,000 inebriates imprisoned in 1907 only 246, or less than 0.5 per cent, developed delirium tremens. Also Wigert²¹ shows that during the Stockholm general strike of 1909, when alcohol was abruptly withdrawn from an entire populace that normally consumed 4.4 million liters of whisky in a year, there was an increase of at most a dozen cases over the average number. Further, Jelliffe and White,²⁰ Noves²² and Bleuler¹⁹ emphasize the point that in the prodromal period of delirium tremens the patient often experiences a disgust and intolerance of alcohol sufficient to cause abstinence for several days preceding the actual onset of the delirium and that this period of abstinence is sometimes mistakenly considered a cause rather than a result of the illness. White and Jelliffe²³ say that "administration of alcohol, either to prevent delirium tremens or as a subsequent therapeutic measure, is both unnecessary and illogical, and, further, tends to perpetuate a false belief in the therapeutic value of alcohol."

We have made a special effort to refute the theory of abstinence delirium, because we believe that it does not deserve the credit almost universally given it and that the ends of rational therapy are defeated when one attempts to treat gross intoxication by giving more of

the intoxicant. Moreover, we believe that a physician is not so likely to be sufficiently diligent in his search for broken ribs, pneumonic consolidations and fractured skulls when he erroneously believes that he already knows what has precipitated his patient's illness. It is our routine practice to withdraw alcohol abruptly, and we have yet to observe any ill results.

NEUROPATHOLOGY

There has been considerable confusion in the reported pathologic changes in cases of delirium tremens. This has been largely due to a failure to differentiate the changes in delirium tremens from those in chronic alcoholism. The dependence of the former on the latter has already been pointed out. It is the prevailing opinion that chronic alcoholism results in definite permanent brain involvement. Although Mott²⁴ was unable to find any specific lesions of the brain in the alcohol addict, Bender²⁵ states that these lesions are "specific both in the type of process and in the localization." She found that the parts most severely involved were those immediately in contact with the spinal fluid. The chief lesion was a productive and invasive ependymitis throughout the ventricular system with "an underlying vascular disturbance characterized by congestion and endothelial proliferation and degeneration, perivascular hemorrhages, capillary budding and organization." Noyes,²² White²⁶ and Ziegler and Horner²⁷ also hold that there are inflammatory and degenerative changes in the brain of the chronic alcoholic addict.

Delirium tremens is a separate pathologic entity arising on the basis of the changes just described. Holtscher,¹⁸ Steinbach,¹¹ Hoppe,²⁸ Strecker and Ebaugh,²⁹ Goldsmith³⁰ and Bogen³¹ believe that cerebral edema is present in delirium tremens, and each has advocated treatment by spinal drainage, of which more later. Lambert¹⁴ considers that cerebral edema ("wet brain") is a clinical and pathologic entity separate from delirium tremens, but this is not the generally prevailing view. Dana³² found cerebral edema and congestion, combined with dilatation of the pericellular and perivascular spaces. He also found that the ventricles are dilated and that the subarachnoid space contains an increased amount of fluid. It would thus seem that edema and congestion of the brain have been almost always found in cases of delirium tremens, and it is on this pathologic condition that we base our present therapy.

THERAPY

The traditional attitude of therapeutic defeatism in delirium tremens is fairly well exemplified by the following statement found in a standard, recently revised textbook of therapeutics:³³ "After one or more days of prodromal uneasiness and insomnia, the patient begins to tremble and becomes actively delirious, in which state he remains without sleep for an average period of five or six days and then slowly recovers or dies." Likewise Osler¹⁶ says that delirium tremens

in a large majority of cases runs a course very slightly influenced by medicine, and Lambert¹⁴ states that there is no specific treatment for delirium tremens. The most commonly recommended measures are baths, wet packs, catharsis, sedation and supportive treatment, with the use of physical restraint when necessary. Paraldehyde is the most widely recommended sedative.

In our hands wet packs have proved dangerous and of little value, and morphine, recommended by a number of writers, including Osler, is distinctly contra-indicated. Likewise we have found physical restraint decidedly harmful and, as we shall show, quite unnecessary.

In the moderately severe and mild cases recovery will probably occur with expectant and supportive therapy or with no therapy at all. The occasional severe case, however, represents a major medical emergency in which the outcome will often be fatal unless the activity of the patient can be checked. These patients are more active in resisting physical restraint than they would be with no restraint, and sedatives alone are practically useless.

Search of the literature disclosed the work of Steinbach¹¹ in Germany (1915), who advocated the use of spinal drainage in all cases of delirium tremens. He found that the course of the illness was nearly always milder and much shorter, that the motor restlessness usually stopped at once, and that the patient usually went to sleep promptly after spinal drainage, without the use of sedatives. Recurrences were treated with the same good result. The most significant advantage of this therapy was the early reduction of excessive activity, which greatly reduced the danger of circulatory collapse and made largely unnecessary the use of supportive measures. This author found that there was increased spinal fluid pressure in 78 per cent of his cases and that when a second drainage was necessary the pressure was again found to be high. He concluded that the increased pressure persists throughout the entire duration of the delirium and related it directly to the pathogenesis of the delirium. His speculations as to the toxic nature of the spinal fluid are interesting. He found that replacement of spinal fluid by physiologic solution of sodium chloride gave the same good therapeutic result and therefore postulated a toxic irritative effect of the spinal fluid on the meninges, and a consequent vicious cycle effect, i. e., the greater the accumulation of spinal fluid the greater the irritation, leading to fatal termination in cases in which the balance was not restored by either natural or artificial means.

The work of Hoppe²⁸ in 1918 in America clearly substantiates the observations of Steinbach. He removed from 30 to 60 cc of spinal fluid in each case of delirium tremens and used mild supportive treatment and alkalinization to supplement the drainage. There was almost always increased spinal fluid pressure in cases in which physical debility was not marked, and in cases in which more than one spinal drainage was necessary the pressure was again found to be high. This author reports his own mortality statistics in 129 cases of delirium tremens and shows that his treatment resulted in a substantial reduction of the prevailing death rate. He states that in the ten year period prior to 1915 the total mortality in delirium tremens was 25.9 per cent and that in uncomplicated cases it was 18.5 per cent as compared with his own total mortality of 10.8 per cent and 7.6 per cent in uncomplicated cases.

More recently (1931) Goldsmith³⁰ has reported similar results in a series of ninety-six cases treated by spinal drainage, with a total mortality of 10 per cent. He agreed with Hoppe and Steinbach that spinal fluid pressure was almost invariably increased and that it remained at high levels as long as the delirium persisted. Also Ebaugh and Johnson³⁴ advised the routine use of spinal drainage in the treatment of delirium tremens. None of these authors observed any ill effect of the spinal drainage method.

Lambert³⁴ prefers to combat cerebral edema in cases of "wet brain" chiefly by the use of ergot. He reports that alcoholic wet brain occurs in about 15 per cent of delirium tremens patients and that about 61 per cent of the cases in which it occurs come to a fatal termination. Klemperer³⁵ and Steck³⁶ used insulin in a small number of cases with good results. They found that small doses of insulin had a sedative action in delirium tremens.

Ebaugh and Johnson³⁴ estimated the mortality at about 20 per cent. Mortality figures quoted by others vary widely. The lowest estimate, given by Henry³⁷ and by Noyes,³⁸ places the death rate at from 5 to 10 per cent. The usual figure given is from 10 to 15 per cent in the uncomplicated cases, rising sharply to 50 per cent in cases complicated by trauma. Schroeder⁹ quotes mortality figures reported by various German authors ranging from 9 to 35 per cent. Certainly it must be concluded, then, that delirium tremens is one of the most serious of medical emergencies.

We shall attempt to show on the basis of 616 cases of alcoholism observed during a two year period (1933-1935) that an alarming death rate in delirium tremens need not obtain, and that such has been the case in the past chiefly because the most effective therapy has been very little in general use. Certain comparisons are made between this group of patients and the group of 605 alcoholic patients admitted during the two year period immediately preceding the period covered by this report.

The treatment used in this study is our own modification of Steinbach's original method, based on the assumption that the increased spinal fluid pressure in delirium tremens is intimately concerned in its pathogenesis and that the most effective method of attack is thorough cerebral dehydration, both by direct and by indirect means. Our routine treatment is outlined as follows:

- 1 Spinal drainage, from 50 to 75 cc. of fluid
- 2 Intravenous dextrose, from 50 to 100 cc. of 50 per cent solution
- 3 Magnesium sulfate, by mouth from 1 to 2 ounces (30 to 60 cc.) of saturated solution
- 4 Limitation of fluid intake to 1,000 cc. for twenty-hour hours
- 5 Paraldehyde for sedation from 2 to 4 drachms (7.8 to 15 Gm.) by mouth or by rectum

This treatment was given, usually on admission to the hospital, in all cases in which there was actual or impending delirium. In those cases in which there was doubt that a delirium existed or was impending, the treatment was limited to intravenous dextrose and water restriction, and to paraldehyde as needed. In

rare cases there was simple acute intoxication, which was treated by sedative doses of paraldehyde or not at all. Alcohol was not given at any time. The result of this immediate treatment was to abort many cases of early delirium tremens, we believe, and these cases were not classified in the delirium group. Many patients were described by relatives or friends as having been delirious before admission but did not have hallucinations in the hospital. These cases also were excluded from the delirium tremens group.

Our diagnostic criteria were the finding of tremor, apprehensiveness and motor restlessness, and the occurrence of visual or auditory hallucinations while in the hospital. The single application of the routine treatment described usually sufficed. Most patients went to sleep immediately after the treatment, sometimes without a sedative, and awoke after from four to six hours of sound sleep, shaky but able to take liquid nourishment. Paraldehyde was ordinarily repeated once or twice particularly at night, and the patient usually showed a prompt return to a stable physical state and was ready for discharge within four or five days. Occasionally it was necessary to repeat the treatment once or twice, and in each case the spinal fluid pressure was elevated, as it almost invariably was in the first instance. Occasionally there was difficulty in obtaining a sufficient amount of spinal fluid to produce a good therapeutic result, and in these cases the drainage was repeated after an interval of from six to twelve hours. In the second drainage there was always a more copious flow of fluid followed by the usual clinical improvement. This type of reaction calls to mind Quincke's theory (quoted by Steinbach¹¹) that elevation of spinal fluid pressure above certain limits causes distortion and blocking of the drainage channels, which is best relieved by direct removal of the spinal fluid so that a more normal circulation may obtain. Perhaps this is the explanation of the freer flow of spinal fluid on the second drainage when little was obtained on the first. Rarely it was necessary to do three or four spinal drainages to control delirium. In the more severe deliriums it was sometimes necessary to give intravenously from 2 to 4 grams (0.13 to 0.26 Gm.) of phenobarbital sodium to help control excessive motor activity and to induce sleep. In such cases we did not hesitate to give these rather large doses since extremes of motor activity are apt to lead quickly to vasomotor exhaustion and collapse and death and the longer one delays such treatment the less effective it is likely to be.

We have had to make all manner of adjustments in our clinical procedure to fit the needs of the various patients. For example, in pneumonia, in which maintenance of body fluid balance is essential, we did not restrict fluids but instead gave more dextrose and kept up the fluid intake to required levels. Occasionally we had to omit spinal drainage in cases in which the physical stress would have been harmful. We might say also that our spinal drainage was carried out with due consideration of the principles of intracranial hydrodynamics. There was of necessity a relatively rapid reduction of spinal fluid pressure, but we attempted always to remove the fluid without causing too sudden decompression. There were no untoward results of this procedure beyond a rare late spinal puncture headache. Masserman³⁸ states that rapid drainage of spinal fluid actually causes cerebral edema and usually is followed by immediate and severe postpuncture symp-

toms, but careful study of his data reveals that by the term "rapid drainage" he refers to forcible aspiration of from 35 to 50 cc in from two to three minutes, for purposes of experiment. In our cases there was never any such rapid drainage as this, and there was never an immediate postpuncture syndrome. However, we are forced to assume that the alcoholic patient is relatively tolerant of spinal drainage, since it seems that postpuncture reactions in our treated cases are actually less frequent than in patients who have had lumbar puncture for diagnostic purposes. We have made no careful study of the number of such reactions in our series, but we feel that the incidence is practically negligible.

RESULTS

By far the most significant result of the two year period (1933-1935) of combined cerebral dehydration therapy was the sharp reduction of mortality in the alcoholic group as a whole, and the lowering of the death rate in delirium tremens to an unusually low level. There was a reduction of slightly more than one half in the percentage of alcoholic deaths to total deaths in the Psychiatric Institute as compared with the two year period immediately preceding that covered by this report, a reduction of from 25 per cent to 12.2 per cent. In the delirium tremens group of 157 cases there were six deaths and in each of these cases a serious illness complicated the delirium tremens. The complicating illnesses were intestinal obstruction, hemorrhagic encephalitis, pellagra, coronary thrombosis and, in two cases bronchopneumonia. Thus the mortality rate in delirium tremens was 3.82 per cent. During this period the alcoholic admission rate and the incidence of delirium tremens and other alcoholic psychoses were higher than at any time during the past five years. We offer no direct comparison of the mortality rate in delirium tremens in the two periods because such a comparison is invalidated by differences in diagnostic criteria. However, no such objection can be made to comparing the results in the alcoholic group as a whole in these two periods. In this group we have included all cases in which alcoholism was an important factor, primary or secondary, all the alcoholic psychoses and all medical and surgical conditions complicated by alcoholism.

During the two years covered by this report the number of patients committed to state hospitals because of chronic alcoholic psychoses was reduced to thirty-two as compared with forty-three during the preceding two years and the number of alcoholic patients released against advice was seven as compared with thirteen during the preceding two years. Furthermore, the average duration of hospital residence in the alcoholic group was reduced from 7.94 days in the earlier period to 6.69 days in the period of this study. It is interesting to note that in the total psychiatric hospital population including the alcoholic group there was an increase in the average duration of hospital residence from 12.98 days in the earlier period to 13.70 days in the later period. Thus we find not only a greatly reduced mortality rate in the entire alcoholic group but also a significant reduction in the number of alcoholic patients committed to state hospitals and a definite reduction in the duration of hospital residence of the average alcoholic patient.

We recognize the objection that statistical comparison between two such consecutive periods, even in the same hospital might not be regarded as entirely reliable because of the fact that the prohibition amend-

ment was repealed at approximately the beginning of the second period. However, we know of no better means of showing objectively the value of our therapy, and we may allow the reader to make his own evaluation of our results in the light of the following considerations. Garvin³⁹, Bigelow⁴⁰ and Gregory⁴¹ found that there was a definite change both in the drinking habits of alcoholic patients and the quality of liquor available during the earlier years of prohibition. Garvin and Gregory observed that alcoholism encountered at that time in hospital practice had changed abruptly from the usual chronic alcoholism seen in preprohibition days to a condition of acute poisoning and that the recovery rate was higher and the ordinary features of chronic alcoholism (polyneuritis, cardio-nephritic conditions, alcoholic hallucinosis and paranoid conditions) were much less frequently seen than in the years before prohibition. They attributed this difference chiefly to the change in drinking habits due to the difficulty in obtaining liquor and, in less degree to the poor quality of the liquor consumed and the use of substitute intoxicating beverages. Gregory states that during the few years prior to 1930 liquor had again become easily obtainable and that the drinking habits of the patients and the character of the alcoholic psychoses were returning to the preprohibition type. According to Jolliffe,⁴² prohibition during its last five years was 100 per cent ineffective in reducing alcoholic admissions to Bellevue Hospital. Moreover, Hunt⁴³ and Lythgoe⁴⁴ reported in 1928 that examination of numerous samples of bootleg liquor revealed that these beverages were no more toxic than was the ethyl alcohol they contained. Both of these investigators reported that bonded whisky was in fact more toxic than the illicit variety and attributed this to the increase of secondary toxic bodies incident to the aging process.

These observations tend to support our own opinion that there was very little essential difference between the two periods other than the therapy employed. Certainly the last two years of prohibition saw little real limitation of the use of alcoholic beverages, and the incidence of alcoholism as revealed by our hospital records changed hardly at all. (In the first period there were 605 alcoholic admissions, and in the second there were 615.) Therefore we feel that this possible factor of error is of little importance, particularly in view of the fact that our results also compare very favorably with recorded statistics in other institutions here and abroad. The degree of error due to prohibition certainly was not great enough to account for all the benefits observed. For these reasons, then, we have ventured to offer a direct comparison of results in the two periods as a fair indication of the value of the outlined therapy.

In addition to our statistical studies we might add some personal observations on the results of this therapy. It was unusual to find a patient who did not experience immediate subjective improvement following the institution of cerebral dehydration, and many patients dated the beginning of their recovery from the time of the initial spinal drainage. Because of the dramatic results ordinarily obtained and probably also because of the tolerance of alcoholic patients for spinal

drainage, most of our patients were grateful for this treatment and a number returned on their own initiative for treatment in the stage of impending delirium. We have also found that there is a remarkable difference in the problem of management of these patients in the hospital since the introduction of this treatment. Formerly the delirium tremens patient was often very difficult to handle, even with the facilities of a psychiatric hospital at our disposal, such was the degree of psychomotor restlessness and overactivity encountered. Occasionally the patient continued for days in a state of increasing excitement and overactivity with a total lack of sleep and little nourishment until circulatory collapse ensued, the temperature rose abruptly to a high level, and the patient died from exhaustion. Since the introduction of the cerebral dehydration routine there has not been a single death of this type. Rather, those who died showed the ordinary terminal symptoms of the complicating or coexisting illness. A most gratifying result of cerebral dehydration treatment was the definite limitation of overactivity that enabled us to dispense entirely with the use of any form of physical restraint. The usual mild early delirium tremens patient actually presented no more of a problem than one might expect from the ordinary general hospital patient. These observations have led us to believe that the ordinary case of delirium tremens might easily be treated in the general hospital, provided early and adequate cerebral dehydration was instituted. With such treatment we believe that transfer to a psychiatric hospital would rarely be necessary. Most of our patients come to us as a last resort after ordinary medical treatment has failed to abort or control the delirium, and no doubt the majority of chronic alcoholic patients in an acute episode are successfully treated at home or in the general hospital by expectant and supportive measures. However, if all such patients were treated as having possible early delirium tremens and given intravenous dextrose, water restriction and saline purges when called to the attention of the physician, we are convinced that there would be a marked decrease in the number in whom delirium tremens develops. If spinal drainage were done at the first sign of impending or actual delirium, few cases would overtax the facilities of a general hospital. In delirium tremens as in many other acute medical conditions, treatment need be much less intensive if begun early.

Finally, we should like to emphasize the inadvisability and the futility of the "tapering off" treatment that is so widely used. As already stated, we believe that alcohol has no place in the treatment of alcoholism. Moreover, the psychologic effect of such treatment on the patient is definitely a harmful one. The alcoholic patient is hardly ever at a loss to rationalize his intemperance, but certainly the weight of medical opinion should not be placed at his disposal for this purpose. This point has been repeatedly stressed in the literature and its importance should not be underestimated.

SUMMARY

1 Delirium tremens is a disease of obscure etiology. No satisfactory explanation of its development on a background of chronic alcoholism has yet been advanced. The concept of "abstinence delirium" has been shown to be erroneous and misleading.

2 The pathology of delirium tremens consists essentially of acute cerebral edema and a consequent increased intracranial pressure. The latter persists throughout the duration of the delirium.

3 A rational procedure for the treatment of delirium tremens consists of cerebral dehydration by spinal drainage and by a brief period of water restriction combined with administration of hypertonic solutions intravenously and by mouth.

4 The results of this method have been uniformly good.

5 We have pointed out the value of this method of treatment in the management of the acutely disturbed delirious patient. We have emphasized that the sedative action of spinal drainage in these cases is particularly suited to the uses of a general hospital. We believe that widespread extension of the therapy in the general hospital field would for the most part obviate the need for psychiatric hospital treatment of delirium tremens.

GARLIC BREATH ODOR

M. A. BLANKENHORN, M.D.

AND

C. E. RICHARDS, M.D.

CINCINNATI

The fetid odor that persists for many hours on the breath of one who has eaten garlic or onions is such a common occurrence that no one has any curiosity about it. Because the odor is so persistent, even though the mouth is clean, the belief has prevailed for many years that the odor comes from the blood by way of the lungs.

The first experimental studies on the disposition of alliaceous essential oils (garlic and onion) in the body were reported in 1930 by Lehmann.¹ He concluded from his studies that during digestion such oils pass into the blood stream, are then aerated from the blood into the lungs, and so pass into the expired air.

The belief in a systemic origin of garlic breath odor is rarely questioned, but recently a report of experiments² from a department of applied physiology was published, stating that such was not the case. The experiments proved, according to the authors, that the odor "arises solely from particles of onion or garlic retained in the structures of the mouth."

Many years ago one of us (M. A. B.) also questioned the assumption that garlic odor comes from the lungs and tested the matter by determining whether or not a garlic breath could occur if garlic was excluded from the mouth. The subject of the experiment was a patient who was suffering from complete stoppage of the esophagus by cancer and who nourished himself through a gastric fistula. The result of these early tests on feeding garlic through a gastric fistula was that the patient did develop a garlic breath every time he "ate" garlic. It seemed quite obvious, therefore, that the odor came in some way from the blood. Since this experiment proved what every one already believed, we did not think enough of our idea to make a report.

Now, however, with newer methods, especially quantitative chemical determinations carried out to the fifth decimal as were recently reported, there is some doubt about the subject which arouses interest. The matter is important as well as interesting because the recent experiments, if correct, have given a way to cleanse the mouth and thereby make the eating of garlic and onions pleasant to every one concerned.

From the Department of Internal Medicine, University of Cincinnati College of Medicine, and the Cincinnati General Hospital.
1. Lehmann, F. A. Untersuchungen über Allium sativum (Knoblauch). Arch. f. exper. Path. 147: 245, 1930.
2. Haggard, H. W., and Greenberg, L. A. Breath Odors from Alliaceous Substances. J. A. M. A. 104: 2169 (June 16) 1935.

We have therefore repeated our experiments on three subjects. Because the chemical methods, recently used to prove that garlic odor does not come from the lungs, were described by the authors as not being specific for onion or garlic, we have resorted to different methods, namely, smelling the breath principally.

REPORT OF EXPERIMENTS

EXPERIMENT 1—W S, who, because of carcinoma of the esophagus, could not swallow anything, including contrast medium for x-ray purposes, was fed garlic soup through a gastrostomy fistula. Lycopodium and methylene blue were mixed with the garlic soup to determine whether or not any of the soup might be regurgitated into the mouth. After three hours and for a period of over twelve hours a strong garlic odor could be detected by all who were asked to smell his breath. Meanwhile saliva and sputum were collected and examined for lycopodium and for methylene blue. None was found. This indicated that the patient had not regurgitated any of his gastric contents, hence the fetid breath could not have come from "particles retained in the structures of the mouth." This experiment was repeated with an infusion of onions and a third time with 0.4 Gm of dipropyl disulfide (garlic oil)³ introduced through a tube lying in the gastric fistula. Each time a fetid odor resulted and no evidence of regurgitation could be found. Seven days after the last test was made the patient died and the pathologist dissected the esophagus for us. He reported that the lumen was obliterated completely and that the membranes were destroyed for 2 inches by a cancer. It was his opinion that the esophagus had been obstructed completely at the time of our experiments.

EXPERIMENT 2—A man, T L, who had had his respiratory tract separated entirely from his pharynx as a result of an operation years before which removed the larynx because of cancer, was given a mixed vegetable salad, including Bermuda onion and garlic. The patient, sent to us by Dr. Iglauer, who performed the operation, breathed comfortably through a tracheotomy fistula and could not in any way exhale his breath through his mouth. If, then, onion or garlic particles might lurk as the residue of his recent meal, such particles could not contaminate his expired air. Three hours and again four hours after eating his salad he was brought to the laboratory and we tested him by smelling his breath. There was a strong and unmistakable odor on the air blown through his tracheotomy wound. This lasted for as long as six hours and could be detected even when the patient kept his mouth firmly closed and an assistant pinched his nose shut. In this circumstance, it was quite obvious that the odor came from the lungs, bronchi or trachea and could not have come from the mouth.

EXPERIMENT 3—This was essentially the same as experiment 2, except that a younger patient was used and the substance given was the essential oil of garlic. R P, a boy, aged 11, was equipped with a tracheal fistula because of stricture of the larynx. There was a small sinus connecting the pharynx with the larynx, but by closing the mouth and pinching the nose it was possible for him to expel the expired air entirely through the fistula and not at all through his mouth or nose. On two occasions a capsule containing 0.4 Gm of dipropyl disulfide (garlic oil) was given and swallowed whole. Three six and twelve hours later the boy was brought to the laboratory where three observers tested his breath by smelling. It was found on each occasion that his breath smelled strongly of garlic even when it was exhaled through the fistula. Breath from the nose and from the mouth gave the same odor but in less degree because the volume of air from this source was very small. Breath from the tracheal fistula in this circumstance came directly from the lungs and could not have been contaminated by mouth odors. A mixed vegetable salad similar to the one used in experiment 2 was given and in two hours and as late as six hours the air expelled through the tracheal opening smelled unmistakably of garlic.

The results of these experiments give strong evidence that garlic and onion odors come from the blood by way of the lungs and do not arise from "particles of onion or garlic retained in the structures of the mouth."

Since the advocates of the latter theory claim that garlic breath odor can be cured immediately and completely by the use of chloramine, a mouthwash containing chlorine, the following study was undertaken to test this hypothesis.

EXPERIMENT 4—Three patients were given garlic in a mixed vegetable salad with their evening meal. Approximately eighteen hours later and after their usual breakfast, a very marked garlic odor could be detected on the breath of all three subjects. Each was then given a 1 per cent solution of a chloramine mouthwash and frequent observations were made on the odor of the breath. For a period of from thirty minutes to one hour the garlic odor was scarcely noticeable and the odor of chloramine was pronounced. However, after one hour and again after the evening meal, a garlic odor could be detected by all who were asked to smell the breath. It is apparent, therefore, that chloramine merely masks the garlic odor temporarily and does not cure it.

COMMENT

In our experiments we have relied on the sense of smell as the method of testing for volatile substances that come from onions and garlic. Since these odors are so commonly recognized, we called to our aid various unbiased witnesses who did not know the nature of the experiment and who, therefore, were not misled in their testing by the "will to believe." These witnesses, who were interns, residents and laboratory technicians, agreed in their replies without significant exception.

Our experiments are all subject to the criticism that no "exact methods" were employed, i. e., no exact chemical assay of the expired air for volatile substances which smell like onions or garlic. On the other hand, the aforementioned experiments, indicating that garlic breath odor comes only from the mouth, are subject to serious criticism in that a nonspecific test was used to prove that a specific substance was absent. This, we claim, is not an "exact method."

In the present experiments we used the best methods possible, namely, smelling the breath, to prove that a fetid substance was present, we also used other very direct methods to prove whence that fetid substance came. Under most circumstances the question of breath odors is complicated by the fact that the breath is exhaled through an opening, the mouth, which is contaminated by the intake of food. In our experiments that complication was surmounted by selecting subjects four in number, who ingested food and breathed through separate openings. This method together with the test of smelling the breath, we believe, is exact and precise and proves with our four examples that garlic and onion odors come from the air passages and not from the food passages. We think these observations are important because they correct misinformation published from a laboratory using exact chemical methods wrongly interpreted. We believe it is important to reopen the question as to whether or not mouth washing will cure garlic breath. We think it will not.

CONCLUSIONS

1. Garlic and onion breath odors come from the blood by way of the lungs and do not arise "solely from particles of onion or garlic retained in the structures about the mouth." This has been demonstrated by experimental studies on four patients who breathed and ingested food through separate openings.

2. Mouth washes merely mask the offending odor and do not cure it.

THE GALVANIC FALLING REACTION
IN PATIENTS WITH VERIFIED
INTRACRANIAL NEOPLASMSEDWIN J BLONDER, MD
AND
LOYAL DAVIS, MD
CHICAGO

Augustine¹ in 1803 demonstrated that stimulation of the ear region by the galvanic current produced falling. By 1874, as a result of the investigations of Purkinje, Hitzig,² Breuer³ and others, it had been demonstrated that closure of the galvanic circuit through the labyrinth produced anodal falling and nystagmus toward the cathode, and that opening of the circuit caused a reversal of the direction of both nystagmus and falling. Further clinical and experimental observations regarding galvanic stimulation by Neumann,⁴ Barany,⁵ MacKenzie,⁶ Alexander⁷ and a host of other investigators resulted in confusing and controversial evidence regarding the value of galvanic stimulation of the ear. The impression gained by many otologists was that when a small amount of current was used the stimulation was limited to the labyrinth. The contradictory clinical results obtained by galvanic stimulation of the labyrinth has caused its infrequent application and observations of galvanic falling have been submerged by the large number of clinical reports on galvanic nystagmus.

In testing for galvanic falling some investigators had the patient stand upright with the feet together or the heel of one foot in front of the toe of the other. Mygind⁸ used the sitting position. Wodak and Fisher⁹ had their patients stand upright with the feet together, arms horizontally forward and eyes closed. The inconsistent results obtained in the clinical application of the galvanic falling reaction have been due to (1) voluntary interference by the patient, (2) a current of large amounts which produced a spread reaction, and (3) pain, which besides being disagreeable produced additional movements to those induced by vestibular stimulation.

One of us⁸ recently described a clinical application of the galvanic falling reaction by the use of a balance board, which proved to be as accurate as the caloric test and produced consistent results. The balance board consists of a platform 16 inches wide, 21 inches long and three-fourths inch thick, under which was a fulcrum 3½ inches wide and seven-eighths inch high. The patient was placed in the normal standing position with the eyes closed, on the platform of the balance board, which was arranged so that a normal patient could maintain his equilibrium without effort. Any change in the patient's center of gravity would immediately be

registered by a lowering of one side of the balance board. Circular moist electrodes, connected to the galvanic machine, were used. For unilateral stimulation of the labyrinth, one electrode was placed on the mastoid and the other on the sternum.

One hundred and fifty-four individuals, including 100 normal persons, were tested for the galvanic falling reaction with the use of this balance board. Closure of the circuit through the labyrinth with from 0.5 to 5 milliamperes, of current resulted in lowering of the platform toward the anodal side with each normal patient. There were no doubtful reactions. The falling obtained was present without a visible nystagmus (convex lenses were not used) and generally without or occasionally with only a slight vertigo, which when present was not rotatory in character. The patients felt as though they were pushed or pulled over. The fifty-four pathologic subjects included nineteen patients with intracranial neoplasms verified at operation by one of us, five patients who are under observation for a suspected intracranial neoplasm, twelve with idiopathic epilepsy, twelve with cochlear defects, six of whom had previous mastoidectomies and six patients with one of the following conditions: labyrinthine fistula, a recently recovered serous labyrinthitis, myasthenia gravis, migraine otitis externa and an acute catarrhal otitis media. Twelve labyrinths in this group of pathologic subjects inactive to caloric stimulation failed to react to galvanic falling when from 10 to 20 milliamperes of current was used. More than 5 milliamperes of current produced pain of varying degrees. In patients who had only one inactive labyrinth the following reactions took place. When the anodal or cathodal electrode was placed on the mastoid with the dead labyrinth, and the other electrode was placed on the sternum, no falling took place with from 10 to 20 milliamperes of current. When the anodal electrode was placed on the mastoid of the active labyrinth, and the cathode was placed on the sternum, closure of the circuit with a small amount of current caused lowering of the platform on the side of the anodal electrode. With the cathode on the intact side and the anode placed on the sternum, falling toward the diseased side took place on closure of the galvanic circuit. These reactions in patients with unilateral dead labyrinth indicated that a single labyrinth can be stimulated when one electrode is placed on the mastoid and the other on the sternum, also that each labyrinth may be negatively or positively stimulated by the galvanic current. The following conditions were present among those patients with inactive labyrinths to caloric stimulation and galvanic falling: basilar skull fracture through the labyrinth, concussion of the internal ear, inactive inner ear following epidemic meningitis, inactive labyrinth following a chronic suppurative otitis media, acoustic neuroma, cerebellopontile angle tumor, and one patient with a right temporal lobe tumor, whose left dead labyrinth was not associated with the tumor.

The nineteen patients with intracranial neoplasms verified at operation by one of us (L. D.) included five with cerebellar astrocytomas, two with acoustic neuromas, four with frontotemporal lobe tumors, one with a frontal lobe tumor, three with parietal lobe tumors, one with a postoperative cerebellopontile angle tumor, which had involved the eighth nerve and one patient with a glioma involving the brain stem. Of these nineteen patients, all but four reacted to galvanic falling. Patients with supratentorial lesions required

less galvanic current than those having an infratentorial lesion, in spite of the fact that those with infratentorial lesions were more ataxic. The average amount of current required to cause patients with supratentorial lesions to fall was 13 milliamperes and 28 milliamperes for patients with infratentorial tumors. Four patients with intracranial tumors, including two with neurinomas of the eighth nerve one with an angle tumor and one patient with a temporal lobe tumor on the side opposite to the dead labyrinth failed to react to falling on stimulation of one ear with the galvanic current of from 10 to 15 milliamperes and also failed to produce nystagmus and past-pointing on caloric stimulation.

To confirm our clinical evidence that galvanic falling performed with the balance board was due to stimulation of that portion of the peripheral apparatus concerned with posture and not due to brain stem stimulation, and that the galvanic falling was independent of nystagmus, two cats were decerebrated by the anemic method described by Pollock and Davis.⁹ The experiments of Magnus and De Kleyn,¹⁰ Pollock and Davis,¹¹ and others demonstrated that the decerebrated cat is an excellent experimental animal with which to test labyrinthine postural reactions because the complicating and inhibitory effects of the higher centers are released. The cat decerebrated above the nucleus of the seventh nerve was placed in the position of maximum extensor tonus, namely, on his back with the nose 45 degrees above the horizontal. The neck reflexes were controlled by fixing the cat's head to the examining table. One electrode was clamped in the ventral midline of the neck. The second electrode was inserted in the auditory bulb in the roof of the mouth. The electrodes were connected to the same galvanic machine that we had used to test galvanic falling clinically. On closure of the galvanic circuit with from 1 to 2 milliamperes of current, extensor tonus diminished in the forelimb toward the anodal side, and simultaneously the extensor tonus in the opposite forelimb increased. Repeated tests with the electrode in either auditory bulb revealed the same phenomena of antagonistic increase and reduction in the extensor tonus in the forelimbs. This experiment is analogous to our clinical test in that the balance board immediately registers the change of tonus in the limbs of the patient stimulated with galvanic current. Our decerebrated animal failed to show nystagmus on stimulation of the ear with galvanic current, with ice water or by turning, because the pathways concerned with nystagmus were destroyed. Since it is almost generally agreed by present-day physiologists that the otolithic apparatus regulates posture, it may be assumed that the galvanic falling reaction is due to otolithic stimulation.

To rule out stimulation of the brain stem by galvanic current as we used it both eighth nerves were cut at the exit of the internal meatus. Ten days later this cat was decerebrated. We subjected this decerebrated cat with section of both eighth nerves to the same galvanic tests as were performed on the first animal. With from 15 to 20 milliamperes of galvanic current no change in extensor tonus occurred on closure of the circuit. When a stronger current was used the current spread throughout the entire animal.

CONCLUSIONS

1 The galvanic falling test with the use of the balance board is an accurate, simple clinical test for determining the integrity of the vestibular postural arc.

2 A series of 154 patients tested for galvanic falling with the use of the balance board indicated that individuals with peripheral labyrinthine defects fail to react to the test. A group of patients with supratentorial tumors required on an average less galvanic current to produce falling than patients with infratentorial tumors.

3 Experimental evidence obtained on decerebrated cats indicated that the galvanic current, as used with the balance board to produce falling, is not localized to the brain stem but has a peripheral action.

4 The galvanic falling reaction appears to be a test for otolithic labyrinthine function, which we hope with the accumulation of a large series of patients with defective vestibular arcs will lead us to isolated lesions in the vestibular postural pathway.

VESTIBULAR (BARÁNY) TESTS IN THE DIAGNOSIS AND LOCALIZATION OF INTRACRANIAL LESIONS

A REPORT OF SIXTEEN PROVED CASES

GEORGE M. COATES, MD
BENJAMIN H. SHUSTER, MD
AND
HERMAN B. SLOTKIN, MD
PHILADELPHIA

Recently one of us¹ presented a review of the practical application of the vestibular tests in otology. We present at this time a group of sixteen cases in which diagnoses of intracranial lesions were made and proved at operation or autopsy. These cases illustrate the added usefulness of these tests in the field of neurology.

Our primary interest in the vestibular studies has been to determine for ourselves, if possible, the accuracy of these observations and the extent of their usefulness in this field. Our examinations, therefore, have been independent of all other data in the study of these cases so that we might be in a position to evaluate them on the merits of these vestibular observations.

In presenting this report it is not our aim to overemphasize the importance of the Barany examination nor is it our thought to minimize the value of any other procedure in the study of these cases. These vestibular tests constitute but one of the links in the chain of studies before a case is submitted for surgical intervention, for there are occasions when all the available information is inadequate in reaching a diagnosis.

It is important to recall that the classic cardinal symptoms of increased intracranial pressure are lacking in many of these patients. Even papilledema considered by many observers the most valuable pressure sign has been shown² to be absent in from 15 to 30 per cent of brain tumors. In a recent report³ of twelve

verified cases of cerebral neoplasm, studied at the University of Nebraska College of Medicine generalized intracranial hypertension was absent in all. Although it is emphasized in that report that more patients die of unrecognized brain tumors than the literature would indicate, and there is a plea for earlier diagnosis of brain tumors by the more general use of the various diagnostic measures, it is noteworthy that no reference is made to the vestibular tests either in their case studies or in the discussions.

We hope to illustrate in this short series of cases the manner in which the vestibular tests may serve to confirm the data obtained by other studies, how they may supply information which gives direction to otherwise apparently conflicting observations, and occasions when they may be the only study to point clearly to a solution when all other examinations give vague, inconclusive or negative results.

It must also be stated, however, that cases are encountered particularly in the supratentorium, in which the vestibular changes are insufficient to justify a diagnosis of a definite brain lesion and yet such a lesion is found at operation, the diagnosis having been made by other means. Even under these circumstances, however, the examination may still be of value in excluding certain well defined areas of the brain as possible sites of lesion, and in this way assist in localization by exclusion.

The cases of brain tumor, which comprise twelve of this series of sixteen will be considered first, the others, four cases of brain abscess, will be taken up as a group subsequently.

Of the patients with brain tumor, four were male and eight were female, all were white. The youngest was 3 years of age, the oldest 54, five were children 15 years of age or under. In their symptomatology, impairment of vision occurred in seven cases. Disturbances in olfaction occurred twice. Headache was a complaint in eight cases. Vomiting occurred six times. Unilateral deafness was present in three, unilateral tinnitus and bilateral tinnitus each occurred twice. Vertigo was a chief complaint in six cases, and disturbance of gait occurred in six. Speech disturbances occurred in two. In one instance, the youngest patient in this group, there were convulsions, and one case presented a history of loss of consciousness.

In three cases symptoms had existed for eight weeks or less, in only five of this group was there a history of symptoms dating back more than six months. One case presented symptoms of ten years' duration and in another they dated back fifteen years.

All these patients were studied between September 1933 and November 1935. Ten of them in the service of Dr. Patten and his colleagues at the Graduate Hospital, came to Dr. Grant's service for operation, of the other two, examined at the Jewish Hospital, one came to Dr. Fay's service for operation and the other subsequently transferred to the University Hospital, was operated on by Dr. Frazier.

REPORT OF CASES⁴

CASE 1.—D. K., a girl aged 12, was admitted to the Graduate Hospital, service of Dr. Peter March 26, 1934. Her chief complaint was impaired vision. She began to lose her vision especially in the right eye about two months previously, when it was noted that she bumped into chairs and other objects.

⁴ We wish to express our appreciation to Drs. Grant, Patten, Yaskin, Alpers and Leavitt of the Graduate Hospital for the opportunity they have afforded us to study their cases. It is only through the cooperation of such neurologists who approach the subject with an open mind and encourage the neuro-otologist in the pursuit of this work that substantial progress can be made in this field.

There had been some mild frontal headache the past few days but no other complaints.

The neurologic report was essentially negative and concluded "All tests for cerebellar disturbance negative" (Dr. Drayton). Ear, nose and throat examination (Dr. Dunn) revealed diseased tonsils and the presence of adenoid tissue.

Eye studies by Dr. Spaeth March 27 showed edema of the disks and engorgement of the vessels and the visual fields showed central scotomas, ocular movements were normal. On April 3 optic nerve atrophy was reported, more marked on the right side.

Roentgen study showed evidence of increased intracranial pressure and concluded "There is possibility of a lesion in the region of the sella turcica but this is not at all positive." All laboratory examinations, including the Wassermann and cerebrospinal fluid, were negative.

Bárány examination was done March 30. The vestibular examination indicated the presence of an intracranial lesion. Localizing signs pointed to the posterior fossa in the midline with pressure on the brain stem from behind.

The vestibular signs of intracranial lesion in this case were (1) perverted responses from the vertical canals on both sides (horizontal instead of rotary nystagmus), (2) marked disproportion between after-turning nystagmus and vertigo, and (3) occasional spontaneous vertical nystagmus on looking up. The complete absence of sensitivity to the tests with the eighth nerves intact in the presence of the foregoing observations pointed to the posterior fossa as the site of the lesion. The presence of good hearing and responses from both labyrinths suggested a midline localization. That there was pressure against the brain stem was suggested by the spontaneous vertical nystagmus, and the markedly hyperactive response and the exaggerated amplitude of nystagmus from all semicircular canals.

She came to operation April 9. Dr. Grant has summarized so beautifully his opinions and the operative observations in this case that we quote in some detail from his report. This girl was a very surprising case. As far as we could see either from her history or from other indications there was absolutely no evidence of cerebellar disease or increased intracranial pressure. Her chief complaint was unexplainable loss of vision. There were apparently no headaches or vomiting. Her neurologic examination was certainly negative on a number of occasions.

Dr. Spaeth reported that she had a postpapillitic atrophy without measurable choking of the disks. The roentgenogram showed very slight separation of the sutures and slight convolutional atrophy anteriorly. I thought she probably had toxic amblyopia from bad tonsils.

We tried three or four days ago to make an encephalogram but the results had been unsuccessful from failure of the air to reach the subarachnoid spaces. Owing to her marked loss of vision I thought we had better determine definitely whether or not she had a brain tumor. A ventriculogram performed in the usual manner showed dilatation of the lateral and third ventricles with block apparently at the outlet of the fourth ventricle. Dr. Duane and I were then of the opinion that she probably had a chronic arachnoiditis blocking the foramen of Luschka and Magendie.

The usual cross-bow suboccipital craniectomy was performed without difficulty and with practically no bleeding. There was considerable fluid and air in the basilar cisternae but the arachnoid was not thickened. The dura was opened over the upper cervical vertebrae, as was the arachnoid. The cerebellar tonsils were then separated and to my great surprise, the nose of a tumor was seen presenting from the fourth ventricle. An incision was made in the vermis and a soft infiltrating tumor occupying the roof of the fourth ventricle and extending down onto its side wall was then exposed.

The operation consisted of suboccipital craniectomy with removal of a midline cerebellar tumor.

In this case the vestibular examination provided the only positive evidence of a brain lesion and correctly localized it in the midline of the cerebellum. It is noteworthy that encephalography and ventriculography were inadequate here either in localizing the lesion or in suggesting the diagnosis. This to our mind is of some importance because of the tendency of some

neurosurgeons⁵ to discount the value of the vestibular tests on the basis that encephalography and ventriculography although attended by greater risk are more helpful than the Barany tests in making a diagnosis

CASE 2—M S, a girl, aged 15 years, was admitted to Dr Patten's service July 6 1935. The chief complaints were headache and vomiting, and a tendency to stagger to either side on walking. There was also a slowing and slurring of words in her speech. There were no eye symptoms and her hearing was normal.

Neurologic examination recorded an ataxic gait, internal strabismus on the left side and nystagmus on looking left. There was some difficulty in articulation. Finger to nose and heel to knee tests were negative. The Romberg sign was positive.

Eye examination (Dr Shoemaker) July 8 showed the left pupil larger than the right and the disks swollen about 3 diopters. Visual acuity was normal.

X-ray examination showed deformity of the sella turcica and evidence of increased intracranial pressure 'such as occurs from a ventricular block the result of a posterior fossa tumor'.

Vestibular examination on the same day indicated a 'midline cerebellar lesion exerting pressure on the brain stem'. The presence of an intracranial lesion was indicated by (1) spontaneous vertical nystagmus (2) perversion from both sets of vertical canals to the caloric test (i.e. horizontal instead of rotary nystagmus), (3) exaggerated nystagmus from both horizontal canals to turning and (4) all nystagmus responses of very large amplitude. The absence of sensitivity to all tests and very poor vertigo and past pointing localized the lesion in the posterior fossa and good hearing and the presence of vestibular responses on both sides placed it in the midline. The spontaneous vertical nystagmus and the exaggerated nystagmus from all semicircular canals suggested pressure on the brain stem.

A suboccipital craniectomy July 13 revealed a cystic tumor arising in the floor and right lateral wall of the fourth ventricle, evidently making pressure on the cerebellum posteriorly. The pathologic report was astrocytoma. The patient was discharged from the hospital July 31 markedly improved.

The significant evidence in this case from the standpoint of localization was contributed by the roentgen and vestibular examinations.

CASE 3—C B, a girl aged 7 was admitted to Dr Grant's service Nov 7 1935. The chief complaints were vomiting, staggering and, at times, impaired vision. She was apparently in good health until three months preceding this admission when projectile vomiting occurred.

Examination of the cranial nerves was negative except for choked disks and lateral nystagmus to right and left. Hearing was normal. There was a tendency to deviate to the left in walking. Cerebellar signs were vague.

Vision in each eye was 6/12—2. The fundus in the right eye was elevated 5 diopters in the left 6. The visual fields showed no gross defects (Dr Spaeth).

Roentgen examination of the skull showed marked widening of all the cranial sutures of the vault. It concluded that there was increased intracranial pressure, probably due to a posterior fossa tumor.

Laboratory studies including examination of the cerebrospinal fluid were negative.

Vestibular examination November 8 limited to the caloric test revealed the following evidences of an intracranial lesion: (1) spontaneous vertical nystagmus on looking up (2) delayed response from the right vertical canals with subsequent perverted and inverted nystagmus (i.e. horizontal to right instead of rotary to left) (3) no response from the left vertical canals and (4) exaggerated and prolonged responses from the horizontal canal on each side. The absence of sensitivity to the tests and the apparent absence of vertigo in the presence of the foregoing observations pointed to the posterior fossa as the seat of lesion, the presence of good hearing and responses from both labyrinths suggested a midline localization. That there was pressure against the brain stem was suggested by the spontaneous vertical nystagmus, the inversion from the right vertical canals and the exaggerated responses from the

horizontal canals. The vestibular diagnosis, therefore, was 'a mass lesion in the posterior fossa, midline, influencing the brain stem by pressure'.

A suboccipital craniectomy was done November 16. Dr Grant reported that the cerebellar lobes were symmetrical, the vermis was only slightly widened. However, when the cerebellar tonsils were separated, the nose of a purplish apparently unencapsulated tumor presented itself at the lower end of the fourth ventricle. The operation consisted of partial removal of a midline cerebellar tumor.

Here again a case in which there was a midline posterior fossa tumor manifested characteristic vestibular appearances. In this case, as in the two previous cases of a similar nature in which midline posterior fossa lesions involved the brain stem at the fourth ventricle, there was a persistent absence of the rotary type of nystagmus that is normally elicited on stimulating the vertical canals. In all these instances the responses from the vertical canals were perverted, i.e. they were horizontal instead of rotary.

CASE 4—S G, a girl aged 6 years, was admitted to the Jewish Hospital, in the service of Dr Schless Aug 21 1934. The chief complaints, of six weeks' duration, were morning vomiting (not projectile) and pain in the back of the head. Two weeks preceding this admission the tonsils and adenoids were removed in another city and no vomiting occurred during the four day stay in that hospital.

Neurologic examination showed the cranial nerves to be normal except for a slight vertical and horizontal nystagmus. There was some ankle clonus on the right side and occasionally on the left. Her gait showed a tendency to veer to the left. The retinal veins were markedly dilated and there was some blurring of the left disk.

X-ray examination of the skull on August 28 was entirely negative.

A Barany study was made on the same date. The vestibular examination pointed to a mass lesion of the posterior fossa near the midline involving the vermis and influencing the brain stem. The vestibular pathways on the left appeared to be more markedly affected at this time than those on the right.

The opinion of intracranial lesion was based on (1) the presence of spontaneous nystagmus, oblique on looking up and rotary and occasionally vertical on looking down (2) spontaneous falling back and to right irrespective of the position of the head and spontaneous past pointing to the right with the left hand and (3) perverted nystagmus from all canals during the caloric test (i.e. horizontal from the vertical canals and oblique upward from the horizontal canals). Its location in the posterior fossa was indicated by the complete absence of shock reactions in the presence of these conditions. The poor pelvic girdle movements and the spontaneous phenomena suggested involvement of the vermis and influence on the brain stem. Abnormal vestibular responses on both sides and good hearing in both ears suggested that the lesion was near the midline, but the very poor response from the left vertical canal to doubling and the hyperactive and occasional perverted nystagmus (i.e., rotary instead of horizontal) on turning to the right—thus testing particularly the left horizontal canal—caused us to suspect that the vestibular pathways on the left side were more markedly affected than those on the right.

The neurosurgical service of Dr Temple Fay advised surgical intervention. The patient refused operation and left the hospital against the advice of the attending physicians.

The child was later found to have been admitted to the University Hospital in the service of Dr Frazier Aug 30 1934.

The various studies at this time duplicated closely the conclusions previously recorded. Neurologic tests for cerebellar dysfunction September 30 were essentially negative.

Operation was finally decided on and on October 5 a suboccipital craniectomy was done by Dr Frazier. The following notes are extracted from Dr Frazier's report: 'Attempted ventriculogram was a failure because the ventricles were not dilated. On passing an exploratory cannula directly backward through the left hemisphere we came to a point of increased resistance 3 or 4 cm beneath the surface. This we interpreted as a solid tumor of the left hemisphere.'

Operative diagnosis: tumor of left cerebellar hemisphere.

⁵ Sachs, Ernest. The Diagnosis and Treatment of Brain Tumors. St. Louis: C. V. Mosby Company, 1931, 134.

The earliest definite evidence of the presence of an intracranial mass lesion and its location in this case was provided by the vestibular examination. Here too it is noteworthy that ventriculography was impossible.

In commenting on this group of cases, it seems to us not inappropriate to suggest that a study which can be entirely objective in its nature, as illustrated in the examination of these four children, which may be conducted by examiners untrained in neurology, and which presents possibilities of usefulness such as are indicated in these case reports, merits a place in the routine examination of these patients.

CASE 5—C G, aged 54, under the care of Dr Leavitt, admitted to the Graduate Hospital Jan. 25 1935 had diplopia and blurred vision for two months, occipital headache, vomiting and weakness of the left side of the face for about six months, and progressive deafness and tinnitus in the right ear and unsteadiness in gait dating back two years. There had been a loss of 35 pounds (16 Kg) during the past year.

The right disk showed an elevation of 15 diopters with engorgement of the veins. There was bilateral concentric contraction in the fields, more marked in the right eye. Neurologic examination showed ataxia in the finger to nose test on the right, a tendency to fall to the right and some weakness of the lower left side of the face. The right ear was deaf.

Vestibular examination, Jan 26, 1935, revealed a condition typical of a cerebellopontile angle tumor on the right side, i e, a nonresponsive right ear with deafness on this side, and no response from the left vertical canals with perverted nystagmus from the left horizontal canal (mixed horizontal and oblique), there were no shock reactions. Spontaneous vertical nystagmus occurred on looking up.

X-ray examination indicated a large shadow in the region of the right cerebellopontile angle.

Operation January 28 revealed a semicystic tumor, containing about 15 cc. of yellowish fluid, which extended from about the level of the vagus up into the cerebellopontile angle on the right side. This was separated from the adjacent nerves and the brain stem and removed.

Here the vestibular observations dovetailed accurately with the clinical, neurologic and roentgen observations in the diagnosis of a cerebellopontile angle tumor on the right side.

CASE 6—L R, a woman aged 26, admitted Jan 3, 1935, complained of pain in the back of her head. There was a history of recurring headaches and vertigo for two years. Hearing in the left ear had been impaired since the birth of a child two years previously, and there had been tinnitus in both ears for several months.

Examination at the Orthopedic Hospital, just prior to this admission, revealed choking of both disks of 3 to 4 diopters, a decreased left corneal reflex, and some weakness of the right lower region of the face. There was no ataxia and her gait was normal. Laboratory studies were negative.

At the Graduate Hospital the right disk was found to be swollen 4 diopters and the left 5. The blind spots in the visual fields were markedly enlarged. Vision in each eye was 6/12. Further examination revealed weakness of the left external rectus and horizontal nystagmus on looking to right and left. X-ray study, showing an erosion of the dorsum sellae and the clinoid processes bent forward, was suggestive of an enlarged or pulsating third ventricle such as might be caused by a posterior fossa tumor.

Analysis of this case at a neurologic conference held January 4 concluded that a cerebellar type of lesion was present but that a more definite localization was not feasible at that time.

Vestibular examination on the same day revealed definite characteristics of a cerebellopontile angle lesion on the left side. The left ear was nonresponsive as to both hearing and vestibular function; there was perverted nystagmus from the right horizontal canal (i e, oblique up and to left instead of horizontal); past pointing and vertigo responses were poor and sensitivity to the tests was absent.

Operation by Dr Grant, January 10, revealed an encapsulated tumor about half the size of a hen's egg involving the left cerebellopontile angle.

'Neurologic examinations in this case pointed to "a cerebellar type of lesion," and roentgen signs were "such as might be caused by a posterior fossa tumor.' The precise localization of a lesion in the left cerebellopontile angle, reported in the vestibular examination was confirmed at operation.

CASE 7—H G, a man, aged 25, admitted Dec. 30 1933, complained chiefly of blindness; there was only light perception. Momentary attacks of dim vision first occurred six months previously. A refraction was done but the vision gradually declined and vertigo developed. Occasional occipital and right temporal headaches occurred during the past month. He had been deaf on the left side since 1931. There was no history of tinnitus, otorrhea or vomiting.

Studies at the Wills Hospital, prior to this admission, suggested a pituitary tumor. Neurologic examination at the Graduate Hospital (Dr Yaskin) concluded that although an angle tumor on the left side was to be considered a definite diagnosis could not be made at this time. Some light perception in the nasal part of the right eye and in the superior temporal part of the left suggested a high degree of right homonymous hemianopia, both disks were raised from 5 to 6 diopters.

X-Ray examination revealed that the deformity was not that commonly seen in the posterior fossa tumors. While this possibility could not be excluded the roentgen signs would be more in favor of a cerebral lesion.

Vestibular examination December 26 pointed to a lesion in the occipital lobe on the left side, which was influencing by pressure the structures below the tentorium; there was no response to the caloric test from either vertical or horizontal canals on the left side and hearing in this ear was almost nil but there was some preservation of the higher tones. Responses on the right side were normal in character but hyperactive with nystagmus of very wide amplitude. Past pointing after rotation was exaggerated and prolonged. There was complete absence of sensitivity to all tests. Spontaneous horizontal nystagmus was present to right and left and a questionable vertical nystagmus occurred on looking up.

Suboccipital craniectomy, December 30, exposed a large tumor behind the cerebellar lobes involving the brain stem and extending forward toward the angle on the left side. But part of the growth could be removed and its complete extent apparently, could not be determined at this time.

Roentgen examinations on two occasions pointed to a cerebral lesion. The visual fields suggested a high degree of right homonymous hemianopia. Neurologic examination concluded that "a definite diagnosis could not be given," although an angle tumor on the left side was to be considered.

Vestibular examination pointed to an occipital lobe lesion on the left side influencing by pressure the structures below the tentorium. This case showed some vestibular characteristics of an angle lesion (i e, non-responsive vestibular function and almost complete loss of hearing on the involved side), but there were other signs which seemed to challenge this diagnosis, i e, markedly exaggerated past pointing (which is usually not present in posterior fossa lesions) and normal or even hyperactive responses from the internal ear on the opposite side.

Operation exposed a large tumor behind the cerebellar lobes and extending forward toward the left angle. Only part of the growth could be removed and its complete extent apparently could not be determined at this time.

CASE 8—E K, a woman, aged 43, was admitted to Dr Grant's service Nov 26, 1934. The chief complaint was blindness for a year and a half. There was history of gradual loss of the sense of smell six years previously and frontal and right temporal headache for ten years.

Eye studies (Dr Spaeth) revealed bilateral primary optic nerve atrophy.

X-ray study of the skull pointed to a supratentorial lesion on the right side.

Only the caloric test was requested in this case. The conclusion was as follows: "There is definite vestibular evidence of an intracranial lesion supratentorial, anterior to the brain stem, and close to the base of the brain. Further localization is near the midline, but inclined more to the left side." Perversion and inversion of nystagmus from the right vertical canals (i. e., horizontal to right instead of rotary to left) and perverted responses from those on the left side (i. e., horizontal instead of rotary) were definite vestibular signs of an intracranial lesion in this case. Its site was the supratentorium, because the presence of very marked shock reactions eliminated the posterior fossa. Perversion of nystagmus from the vertical canals of both sides pointed to a midline position, but the added inversion of responses from the right vertical canals—in a supratentorial lesion—suggested that the lesion was more inclined to the left. Exaggerated and prolonged responses from all semicircular canals and the inverted response suggested a location close to the base of the brain and influencing the brain stem.

She came to operation December 6. Dr. Grant reported that "a probe introduced through the cortex of the left frontal lobe encountered a hard tumor mass at a depth of about 2 cm. Removal of the cortex in this region revealed a tremendous meningioma lying in the midline, involving the olfactory groove, and extending upward from the base of the brain." An olfactory groove meningioma lying on both sides of the falx was removed.

This patient subsequently developed an edema of the brain, which resulted fatally.

It is of some interest to speculate whether vestibular studies early in the progress of this case might not have suggested the lesion and thereby enhanced the possibility of successful surgical intervention.

CASE 9—C. B., a man, aged 43, admitted to Dr. Grant's service Feb. 7, 1934, had occasional headaches and vertigo for fifteen years but worked as a street car conductor without interruption until five months before this admission, when his eyesight began to fail and the headaches became more severe and more constant. Recently he had noticed peculiar odors and tastes which he could not explain, had become weak, and had lost considerable weight.

Neurologic examination by Dr. Alpers threw suspicion on a tumor in the left frontotemporal region. Examination of the eyes revealed a right homonymous hemianopia and an elevation of 2 diopters in both nerve heads.

X-ray studies at the Graduate Hospital, and also at the Orthopedic Hospital prior to this admission, were entirely negative.

Vestibular study, limited to the caloric test, suggested a left sided supratentorial lesion. There was perversion of responses from the vertical canals on the right side (i. e., horizontal instead of rotary) and a normally responding left ear, the posterior fossa and angles were eliminated by the presence of good hearing in both ears and the fact that responses passed through both internal ears and eighth nerves, sensitivity to this test was slight and there were no abnormal spontaneous manifestations.

As the patient was becoming stuporous and the temperature, pulse and respiration were rapidly mounting, operation was decided on. His condition permitted only decompression through a left temporoparietal craniotomy. The case subsequently came to autopsy and revealed a large glioma occupying the left temporoparieto-occipital region.

In the repeated absence of x-ray evidence of a brain lesion the vestibular observations in this case confirmed the neurologic and eye examinations in the diagnosis of a supratentorial lesion on the left side.

CASE 10—J. G., a man, aged 29, admitted to Dr. Grant's service Jan. 16, 1934, first noticed blurring of vision four months before. About ten days later severe frontal headache developed and 'buzzing' started in his ears especially in the left ear. He then complained of attacks of dizziness and there was a tendency to fall to the left. There was difficulty at times in finding words with which to express himself.

Neurologic examination was inconclusive, suggesting 'either a right supratentorial lesion or a left infratentorial lesion.' Eye studies (Dr. Spaeth) revealed a vision acuity of 1/60 in

both eyes and a papilledema of 3 diopters. There was a right homonymous hemianopia, confirmed by reexamination, which pointed to a left sided lesion. The cerebrospinal fluid was under 20 mm. of mercury pressure and showed an increase in globulin.

A partial vestibular examination in this patient pointed to a supratentorial lesion on the right side. The presence of good hearing and, after stimulation, response from both horizontal canals, vertigo, normal past pointing and sensitivity excluded as possible sites of lesion the posterior fossa, cerebellopontile angles, eighth nerves and both labyrinths. Very marked exaggeration of the nystagmus (fifty-three seconds) with disproportionate diminution of vertigo from the left horizontal canal (on turning to the right) tended to localize it on the right side.

X-ray examination and a ventriculogram indicated a large mass lesion in the right temporoparietal region.

Operation January 20 disclosed a large glioma lying inside the right lateral ventricle and extending forward under the motor cortex.

The results of the neurologic examination in this case did not permit of a definite diagnosis, while the ophthalmologic studies pointed to a left sided lesion. Vestibular manifestations pointing to a right sided supratentorial lesion, were supported by the x-ray examination and ventriculogram and were confirmed at operation.

CASE 11—E. T., a girl, aged 3 years, was admitted to the Jewish Hospital Aug. 25, 1933, with convulsions. She was apparently in good health until eight weeks before this time, when there was a history of a cold and a convulsion occurred four hours later the child apparently lost the use of the right arm and leg. She was admitted to the Mary Drexel Home where the symptoms soon disappeared. Spinal fluid, Wassermann, blood and urine, and eye examinations were negative, and she was returned home in four days. During the following week there were momentary twitchings of the right side of the mouth and face. Gastro-intestinal disturbances then occurred with vomiting (not projectile) and moderate fever, and the child was admitted to the hospital.

The usual studies, including the neurologic, were essentially negative, except that the eyegrounds showed an optic neuritis and a possible choking of both disks. The cerebrospinal fluid was normal and under 6 mm. of mercury pressure.

August 30 the caloric test, by mass douching, showed delayed responses from the vertical canals of each side with very poor responses on the left. This was strongly suggestive of increased intracranial pressure but of little localizing value, and it was suggested that the test be repeated in a few days. The child appeared comfortable at this time and seemed to act normally for a child of her age. Before the test could be repeated, however, the vomiting recurred, she became drowsy, and a slight right hemiparesis developed.

September 2 an emergency decompression was done by Dr. Temple Fay's service. The dura was found thickened and under great tension. Splitting of the dura disclosed a large glioma in the left frontoparietal region, and this was shelled out. The child died the following day.

In this child all the studies were inadequate in establishing a diagnosis. The optic neuritis, revealed in the eye examination, was accompanied by but little choking of the disks. The vestibular manifestations, although not of localizing value in this case, did suggest the increased intracranial pressure reflected in the terminal symptoms and operative disclosures.

CASE 12—R. S., a youth, aged 18, was admitted to Dr. Grant's service with the chief complaint of 'headaches.' His first illness occurred in 1930 three years preceding this admission, when he suddenly became dizzy, developed severe headache and lapsed into unconsciousness. He remained unconscious ten days, with periods of violence which required restraint. When he recovered from this 'spell' there was marked weakness and the vision in his left eye was almost entirely gone. An eye study at that time showed marked pallor of the left disk and vision in the left eye was limited to motion. Vision in the right eye was normal.

This continued about five months, when he began to have severe frontal headaches and attacks of vomiting. Following an operation on the left ethmoidal sinuses at that time these symptoms subsided and aside from the loss of vision in his left eye, he remained comfortable for a year. Headache and vomiting then recurred with increasing severity and frequency.

Our vestibular examination revealed signs of an intracranial lesion, supratentorial, anterior to the brain stem and influencing it, and probably in the midline. The vestibular signs of an intracranial lesion were (1) absence of response from the vertical canals on both sides in the presence of good response from both horizontal canals and good hearing, and (2) occasional dissociated eye movements. Marked sensitivity to the tests pointed to the supratentorium as the site of the lesion, and obliteration of both sets of vertical canals suggested a midline position. The tendency to dissociation of eye movements suggested an influence on the brain stem (i.e., pons).

Transfrontal craniotomy by Dr. Grant resulted in the exposure and partial removal of a suprasellar tumor believed to be a meningioma. The patient subsequently was discharged improved.

A point of added interest in this case is that the symptoms, including those of the eyes, were at first thought to be secondary to sinusitis. Following operation on the sinuses the patient remained comfortable for a year. The associated symptoms then recurred and eventually the case proved to be one of brain tumor.

Following is a group of four cases of brain abscess—three of otitic origin and one case secondary to frontal sinus infection—in which vestibular tests (either the complete examination or the caloric test alone) were done sometime during the course of the illness.

CASE 13—S. F., aged 10, presented a chronic suppurative otitis media on the right side with involvement of the mastoid. Simple mastoidectomy was done without apparent improvement. There was a prolonged postoperative illness with fever, loss of weight and headache, and various intracranial complications were suspected. The lateral sinus was opened and the internal jugular vein ligated but pus was not found. The right temporosphenoidal lobe and the right cerebellum were searched for abscess but none was found. There were no localizing neurologic signs until shortly before the patient died.

Eleven days before the appearance of the first localizing neurologic sign (astereognosis) a caloric test revealed on the right side (1) delayed response from the vertical canals and (2) when the head was tilted backward to test the horizontal canal, instead of a horizontal nystagmus there appeared vertical nystagmus upward (i.e., perversion). Responses on the left side were normal.

At postmortem an abscess was found in the right temporoparietal region and another deep in the right cerebellum.

CASE 14—W. B., aged 11, gave an indefinite history of trauma to the head followed by right frontal sinusitis. The patient complained of persistent headache and vomiting, and a right frontal lobe abscess was suspected. There were no localizing neurologic signs.

A complete vestibular study revealed (1) very poor pelvic girdle resistance, the patient falling like a stick at the slightest tilt; (2) marked hyperirritability on turning to the left (stimulating the right horizontal canal); (3) delayed response to the caloric test on the right side (one minute thirty seconds); and (4) very significant persistent past pointing of the left hand following each stimulation as if that hand had escaped the volitional control of the brain. In contrast the right hand past pointed normally.

Based on the poor pelvic girdle reaction and the peculiar behavior of the left arm during past pointing with the delayed response from the right vertical canals a diagnosis was made of a right frontal lobe abscess influencing the motor area. Sensitivity to the tests was absent, an unusual finding in frontal lobe lesions. At operation a right frontal lobe abscess was found. Postmortem revealed this abscess to be well encapsulated and about the size of a small hen's egg.

There was a possibility of confusing these vestibular observations with those of an occipital lobe lesion but the type of bizarre past pointing manifested by the left hand was unlike

that found in occipital lobe lesions, which are characterized by exaggerated distance of past pointing, ataxic in character due to pressure on the cerebellum from above. In this instance, however, the distance of past pointing was small but its persistence for a very long time seemed to indicate a loss of volitional control.

CASE 15—P. F. was a man aged 31, in whom a diagnosis of left temporosphenoidal lobe abscess was made and confirmed at operation. A caloric test preceding operation showed complete absence of responses from the vertical canals on the affected side, all other responses were practically within normal limits.

CASE 16—M. K., a girl, aged 17, with a history of bilateral otorrhea since infancy, presented symptoms that were suggestive of brain abscess. Neurologic roentgen and eye examinations revealed no evidence of intracranial involvement. Barany examination, however, showed definite vestibular evidence of intracranial disturbance: perverted responses from the horizontal canals to both the rotation and caloric tests (i.e., rotary instead of horizontal nystagmus, also mixed rotary and oblique nystagmus from the left horizontal canal after douching). The presence of sensitivity to the tests pointed to the supratentorium, and the more bizarre responses from the left horizontal canal tended to indicate more particularly the left side of the brain.

Exposure of the middle fossa on the left side July 10, 1934, revealed the dura under marked tension. Subsequent exploration disclosed a left temporosphenoidal lobe abscess.

These cases of brain abscess are presented merely to show that they do manifest vestibular signs of an intracranial lesion. While their localizing value is not as satisfactory as in brain tumor possibly because the pathologic condition here is more rapid and less space taking than in brain tumor, nevertheless these vestibular signs of intracranial involvement at times are present long before there is any localizing neurologic sign.

This conclusion is in accord with that of the late S. McCuen Smith,⁶ who reported his experiences in the diagnosis and localization of brain abscess of otitic origin. He detailed three cases in which vestibular tests were done prior to operation. One case of cerebellar abscess showed vestibular changes typical of a cerebellopontile angle lesion. A second case showed absence of responses to the caloric test from the vertical canals of both sides. His third case (as with our case S. F.) yielded a perverted response to douching from the horizontal canal on the affected side (i.e., a vertical instead of horizontal nystagmus appeared on tilting the head back).

In summarizing his experiences with the vestibular tests in the diagnosis of brain abscess Dr. Smith stated at that time: "They are useful in that frequently they are the only tests that indicate with any degree of definiteness the presence of intracranial involvement."

SUMMARY AND COMMENT

In this series of sixteen cases—confirmed at operation or autopsy—are presented (1) three with midline posterior fossa tumor involving the fourth ventricle, (2) one case with tumor of the left cerebellar hemisphere, (3) three cases of mass lesion involving the cerebellopontile angle, (4) five cases of tumor above the tentorium involving the olfactory groove, the temporoparieto-occipital area, the temporoparietal lobe, the frontoparietal area and the suprasellar region, respectively, and finally (5) four cases of brain abscess, one involving the temporoparietal lobe as well as the cerebellum, one in the frontal lobe and two with temporosphenoidal lobe involvement.

This report emphasizes the usefulness of the vestibular examination as an aid in the diagnosis and

⁶ Smith S. M. Consideration of Otic Brain Abscess with Special Reference to Diagnosis and Localization. *Laryngoscope* 34: 534 (July) 1924.

localization of intracranial lesions. It illustrates the manner in which these tests may serve to confirm the data obtained by other studies, how they may supply information which gives direction to otherwise apparently conflicting observations and occasions when they may supply the link that makes possible diagnosis in a group of cases among the most difficult and fraught with the most tragic consequences in the entire field of medicine.

With some lesions, as with those involving the cerebellopontile angle, the vestibular examination often makes possible diagnosis before the appearance of general clinical phenomena and at a time when operation promises the best results. Since tumors of the cerebellopontile angle comprise a large percentage of all brain tumors, a test that is so helpful in either localizing them or excluding them from this region is of the utmost importance. The consideration of angle lesions is of particular importance to the otologist, since the initial symptoms, as a rule, are deafness and tinnitus and the otologist is the first physician consulted.

In closing we should like to urge the cooperation of those concerned in the management of these cases to the end that not only there may be recorded a vestibular examination in their study but that the neuro-otologist may be given the opportunity to compare his observations with those at operation or, even more important, at autopsy, for it is not uncommon for a tumor or brain abscess to remain hidden at operation and its presence be revealed only subsequently at necropsy.

It is only by such opportunity to examine a large number of cases and to check the results that the vestibular examination may be interpreted with greater accuracy, that localization may be made with greater precision, and that diagnosis may be suggested at an earlier stage in the progress of these lesions.

1721 Pine Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. BLONDER AND DAVIS AND DRS. COATES, SHUSTER AND SLOTKIN

DR. WINCHELL MCK. CRAIG, Rochester, Minn. The difficulties encountered in accurately diagnosing and localizing intracranial lesions are frequently so great that any refinement or innovation in the testing of the cranial nerves which will tend to expedite the situation is very welcome. The double function of the acoustic nerve makes it extremely important from the standpoint of the various tests and especially is this true of the vestibular portion. This nerve carries impulses from the semicircular canals to a number of nuclei in the medulla, dorsal auditory nucleus, nucleus of Deiter and nucleus of Bechterew, with a few fibers passing directly to the cerebellum and other fibers connecting with the motor nuclei of the ocular muscles and vestibulospinal tract. The different ramifications often complicate an attempt to differentiate any dysfunction in contrast to the normal. A careful study of a series of cases is of value in clarifying controversial points and I think the papers of Drs. Coates and his colleagues and Drs. Blonder and Davis may prove of great value in allowing for a more complete examination. However, several anatomic facts which influence the diagnostic value of these tests should be kept in mind in evaluating them. The vestibular nuclei lie very close to the floor of the fourth ventricle, so that any pressure on the fourth ventricle is very likely to produce dysfunction. The most important sources of error in interpreting the results of these tests are due to the fact that the pathways through which the vestibular nerve acts are crowded together in the floor of the fourth ventricle and pons. A large percentage of tumors of the posterior fossa very soon cause an obstruction to the aqueduct of Sylvius and the accumulation of cerebrospinal fluid in the ventricles compresses these pathways. When little or

no internal hydrocephalus is present, as in acoustic neuromas or other tumors of the cerebellopontile angle, these tests may be of great value. It is true that the results of all special tests must be considered in conjunction with the complete general and neurologic examination, as one is sometimes prone to emphasize certain symptoms and place undue diagnostic importance on tests the results of which do not fit into the picture as a whole. It is generally agreed that intracranial tumors are being seen at a much earlier stage of development than formerly and that reliance must be placed on a finer differentiation of tests that have been used or on the development of new tests, which will be of greater value in making a differential diagnosis and aiding in localization. Many advances in neurosurgery have been made possible by studies such as these carried out in the special allied fields, and it is by continued cooperation in efforts toward a more accurate and comprehensive diagnosis that the entire field of medicine, and especially neurology and neurosurgery, is being advanced.

DR. CLAUDE T. UREN, Omaha. These papers show what cooperation between neurologists and otologists can produce and yet only recently an eminent neural surgeon in the discussion of a paper on vestibular vertigo said that he would not subject a patient with a possible intracranial lesion to the Barany tests because of possible serious results from a severe reaction. The Barany tests have a distinct advantage over some of the other physiologic tests in that the responses resulting from the tests are not under voluntary control of the patient. The evaluation and interpretation of the results are under the control of the examiner and a careful evaluation of the subject and his responses are necessary in order that the test may be of value in diagnosis. One who is hypersensitive to motion and gives a history of car sickness or sea sickness is most likely to show violent reaction from the test, while a subject normally hyposensitive to motion or with a heavy, thick, bony labyrinth or chronic thickening of the drum and tympanic mucosa will show delayed responses to the caloric test. These facts should be considered before a diagnosis of supratentorial or infratentorial lesion is made. Vertical nystagmus up or down, perverted nystagmus, inverted nystagmus and oblique nystagmus are found with rare exceptions only in intracranial disease. An analysis of the cases reported by Drs. Coates, Shuster and Slotkin show how frequently these types of nystagmus are found in cases of brain tumors and their importance in the diagnosis and localization of brain lesions. Absence of vestibular responses from one side, together with absence or perversion of responses from the opposite side, is most often indicative of an intracranial lesion. The so-called angle syndrome, supposedly diagnostic of tumors of the cerebellopontile angle, has been reported in cases of brain concussion and multiple sclerosis and is by no means constantly found in angle tumors. The cochlear portion of the eighth nerve should not be overlooked as a guide to intracranial troubles. In increased intracranial pressure there is a falling off of the high frequencies sometimes without noticeable loss of hearing. In many extracerebral lesions there is found a loss of hearing on the affected side, and in the case of pontile angle or acoustic nerve tumors the loss of hearing is usually an early symptom which in spite of confusing contralateral nerve symptoms is often of importance in diagnosis and localization. The paper of Drs. Blonder and Davis may prove beneficial in differentiating peripheral from intracranial lesions.

DR. J. CHARNLEY MCKINLEY, Minneapolis. In our experience with the Barany tests at the University of Minnesota Hospital, my associates and I have often been confused in attempting to localize a lesion of the brain and have tended to depend more on the total neurologic configuration. I do not mean to say that we have never had help from the Barany test. Since the series of cases presented by Drs. Coates, Shuster and Slotkin indicates a surprisingly great reliability of these tests, I should like to ask a question or two. First have they had any cases in which they could not make a diagnosis by means of the vestibular examination alone? Second I understand perfectly well that the authors have not had time to go into the neurologic examination but I wonder how much additional help in focal diagnosis came from the neurologic examination in these cases. I would emphasize with Dr. Craig that the vestibular tests refer to one portion of one cranial nerve and constitute simply one phase of the neurologic investigation.

DR SAM E. ROBERTS, Kansas City, Mo I am happy to see that Dr Coates and his co-workers are going ahead with the splendid work that Dr Fisher started In his report of more than 100 cases in 1928 he proved his angle syndrome and it has not been disproved since There are other conditions that will produce it It is, however, a valuable neurologic sign No one ever maintained that these tests are final, they are only aids to the other neurologic examinations Last year we had two cases at the University of Kansas Hospital, one a child under 2 years of age in whom we made a diagnosis of a midline lesion As near as we could tell the child's hearing was normal Douching produced no response on either side from the vertical canals We got beautiful responses from both horizontals We made the diagnosis of the midline lesion and stopped there It was shown at autopsy that it was a midline lesion and in the vermis Inside two months we had a similar case with identical vestibular observations in a child 10 years of age In this case we knew positively that the hearing was normal because we could make functional tests, while with the baby we could not We made a diagnosis of midline lesion, probably vermis At operation a vermis tumor was found I don't recall in Fisher's classic report whether he mentioned the vermis lesions or not, but we had two in such a short time at the university that we were all impressed with the importance of these observations

DR EDWIN J BLONDER, Chicago I regret that no direct questions were asked with regard to the galvanic falling test The reason we brought up this matter is that we hoped that this test will differentiate those cases with lesions affecting the postural vestibular tracts from those in which lesions are present in the tracts concerned with production of nystagmus, when the ears of a large series of patients with intracranial neoplasms are examined galvanically One of the discussants mentioned cooperation between groups This is quite evident in our paper, for the co-authors are a neurosurgeon and an otologist All the patients were completely examined by a neurologist, usually Dr Lewis J Pollock and Dr Loyal Davis and I conducted the ear examinations We utilize all ear tests in the analysis of the case and have found to date that our galvanic falling test has given us similar responses to those resulting from caloric stimulation The point was brought out that sometimes the Békány test could not be used just before an operation In that regard we have used the galvanic falling reaction from twelve to twenty-four hours before an operation, and I have also performed the test on patients from ten days to two weeks after an operation There are no violent or disagreeable reactions with the galvanic falling test We have repeated the test from time to time on the same individual, with the same results While these patients were at the hospital, the galvanic falling test did not interfere in any way with the other examinations that were being conducted

DR GEORGE M COATES, Philadelphia We have presented nothing new in this paper but have tried to emphasize the fact that the vestibular tests are of value in the diagnosis of intracranial lesions Our interest was stimulated because a recent paper by a well known neurologist discussing intracranial diagnosis in a large series of cases failed to show that these tests had been utilized They are not in themselves sufficient to make an operative diagnosis but should support or be supported by every other method known in neurology These tests are not difficult to perform, and if done systematically and if the information obtained is charted under a definite but simple system much valuable knowledge may be obtained In this small series of proved cases we have given our preoperative vestibular examination diagnosis which was made without consulting the neurologic examination until afterward This was done to satisfy our own minds We have attempted a broad and very simple classification of observations which was long ago worked out by Dr Shuster What Dr Roberts has said is perfectly true These observations are not absolutely diagnostic They are only suggestive I fear neurologists have the feeling that we otologists have claimed for our methods a better way of diagnosing intracranial lesions than their well tried and proved methods have been and that at times they have become somewhat antagonistic This is far from being the case We claim only that the vestibular tests will often—not always—be of help and that in these obscure cases only too often all available methods are not sufficient to give the neurosurgeon an exact

localization Dr McKinley asked whether there were cases that we could not diagnose by these methods Yes indeed there were These methods, after all, are only suggestive As a rule we make no attempt to reach too close a diagnosis These diagnoses were made for our own information to see what we could do without the help of the other examinations, and we report them as such The neurologic observations are all in the full paper, which, of course, we did not have time to report here Dr McKinley also asked whether we had any help from the neurologists Indeed we did but only after our neurologic diagnosis had been definitely recorded We simply reported this as a vestibular test study to see what we could do and to make this plea for more cooperation between the different branches that have to study these cases of intracranial lesion They are difficult enough, and many times all our methods are not sufficient to arrive at a diagnosis, they have to be studied over and over and over again, but we do feel that vestibular testing is of decided help

THE MODERN HEALTH RESORT

AN APPRAISAL OF ITS POSSIBILITIES

ALBERT W WALLACE, M D

WATKINS GLEN, N Y

What is the status today of the modern health resort in medical practice? What value does it have? What does the "cure" consist of? Can the spa offer more to the patient than just a mineral spring with "beautiful gardens and an excellent band," as Sir James Mackenzie thought? In these days of purely scientific medicine, can the spa be as great a therapeutic factor as it was in more empirical medical days?

Such questions are of prime importance to the physician who contemplates referring a patient away for a "cure" Unfortunately, many physicians believe that the spa offers no more than it did in the early Greek and Roman days, namely, a mineral spring water that is either taken internally or used externally for a course of baths While most resorts are located at or near natural mineral springs the waters of which are used for treatment purposes, this feature of the spa regimen is only one of many advantages such resorts should offer the physician and his patient It is not my purpose to discuss here the various types of waters found in this country or abroad or to discuss the use to which they are put Many articles have been and are being written describing the use and efficacy of such waters and references are readily available Rather is it my hope to describe here those additional features which all resorts deserving of medical confidence should share in common—features which far outweigh the value of the waters alone and thus make the use of these waters per se often of secondary rather than of primary consideration when it comes to referring patients away for a "cure"

The position of the health resort of today is a unique one midway between the home and hospital environment It has advantages of both without many of their disadvantages It cares for people who should be isolated from home and business and yet do not need the specialization or the atmosphere of hospitalization The true health resort is not a diagnostic clinic or a research institution Its position in modern medicine is a very definite one and its limitations are sharp and well defined Its clientele should therefore be selected with care, the referring physician realizing its limitations as well as its value to the patient

What should the physician expect from a health resort for his patient and how best can the spa serve him? Unfortunately the American Medical Associa-

tion has not as yet laid down qualifications for such resorts, so that the referring physician, unless he himself knows the resorts or has made a study of them, is often unable to decide to which one he can with confidence send his patients. There are certain features which these resorts should have in common, regardless of their mineral springs, in order to serve the patient best. Such features are based on hygiene in its broadest sense and should include competent medical supervision, a proper dietary, systematic rest, regulated exercise, a proper knowledge of the reserve the patient possesses so that he can live sanely within that reserve, and proper physical therapy, hydrotherapy and electrotherapy given by competent attendants, the whole to be so planned and regulated that the patient's day is entirely occupied. Psychic elevation of the morale and the development of a proper philosophy toward the disease from which he suffers should be additional features the spa should see accomplished for the patient.

COMPETENT MEDICAL SUPERVISION

Of prime importance to the home physician is whether or not his patient will receive competent, ethical medical care while away, so that he can with perfect confidence advise that patient to be separated from him. Confidence must exist between the spa and home physicians, so that the suggestions of one will be mutually respected by the other. The spa physician often has certain advantages for the patient's care which the home physician cannot have, for he sees the patient intensively every day. He lives with the patient and knows how he spends his time, how and what food he eats, when he goes to bed, and how well he sleeps. He knows his domestic problems and his habits and from all this is able to treat him intelligently as a real individual with an individual problem. It is only through competent medical supervision that the features hereafter described can be supervised and directed for the patient. It is only through competent medical supervision that the correct regimen can be laid out for the patient, so that he will obtain the greatest possible benefit from his "cure."

PROPER DIETARY

There is no greater service the health resort can give, nor one more open to fad, than that of the dietary. Probably no subject can today be more readily or easily exploited in medicine than the problem of nutrition. It is not enough to give him a list of "foods allowed" and "foods to avoid" and then dismiss the subject. The ordinary person, either sick or well, is intuitively interested in the subject of a correct diet. He usually finds it difficult to follow such a diet list alone, or else makes an honest effort to do so only to be enmeshed in a hopeless maze of foods and calories. It is the duty as well as the opportunity of the health resort not only to see that the patient receives the proper food but to go further and instruct him so that he can carry on after he goes home without undue effort and caloric arithmetic. The ethical resort has plenty to do in the way of dietary if it follows conservative, legitimate and well known laws of nutrition without capitalizing on the layman's gullibility for food fads.

ELIMINATION

The "drinking of the waters" has always been a prominent spa feature. Most resorts have natural springs of a cathartic or diuretic action which the patient sips as he takes his early morning walk. No discussion of such waters will be given here. Suffice it to say that the use of such waters should be taken

on prescription only and that, while attention to elimination is always of importance, daily purging by saline cathartic waters is more often to be condemned than encouraged.

SYSTEMATIC REST

Opportunity for an abundance of rest is the secret back of the success of many resorts and is a feature *par excellence* that all spas should offer. Rest is obtained in three ways. First, the whole tempo of life at a spa is slow. Second, at least one hour's rest after all treatments is compulsory and is recognized as an integral part of the "cure." It is this rest period following a treatment, whether it be a bath or massage, which gives to that treatment its greatest value. An relaxing treatment is valueless if no rest follows it. Similarly a hot treatment, as a cabinet or pack can be dangerous if rest following it is not insisted on. Many of the larger hotels have today installed apparatus for treatment by hydrotherapeutic and physical therapeutic means. These treatments have in many cases done considerable harm rather than good, not only from their indiscriminate prescription but also from a failure to insist on a proper rest period following their use. Early to bed constitutes the third method of obtaining rest. There is a mass psychology for the patient taking the cure, which makes that patient want to retire early with the result that an abundance of rest during the twenty-four hours is assured for him.

REGULATED EXERCISE

Regulated exercise is of enormous value to all individuals and can be carried out with success at the resort, for here are found the time, facilities and supervision for it. Passive exercise in the form of the Zander apparatus, and active exercise in the gymnasium or in the form of golf, horseback riding or tennis, for those able to take these strenuous forms, should be available. For the incapacitated, passive exercise in the form of massage, and later the selective active resistance exercises of Schott, give a substitute for the active forms. Simple walking is the most popular form of exercise and the form best suited to the majority of patients at the spa. This form of exercise is encouraged by having definite graded and measured walks, so that the physician can tell which walk to take and then note the response knowing exactly how far and on what grade that patient has been. Such walks have the advantage too of determining the reserve each patient has, so that he learns exactly how far he can exercise with safety to himself. A definite time as well as amount and type of exercise should be prescribed, as it is considered as definite and curative a part of the regimen as any other single procedure.

KNOWLEDGE OF RESERVE

How much leeway can a patient have with perfect safety to himself and his disease? During a "cure" period such a question should be satisfactorily answered for that patient. This applies particularly to heart patients. Nothing will do more to prolong the life of an ambulatory cardiac patient than a proper knowledge of his myocardial reserve, so that he can live within it. Heart patients must be taught to live with the hearts they have live within the reserve which that particular myocardium possesses, know the signs which warn them that they are overstepping. The majority of heart patients however have not been taught their own limitations most of them either overstepping and getting into difficulties or else going to the other extreme and making needless invalids of themselves. The response to graduated walks and other forms of

activity coupled with daily intensive observations on the patient should enable the spa physician to determine accurately the patient's reserve and impart that knowledge to him so that he can live with the greatest comfort and longevity

PHYSICAL THERAPY AND HYDROTHERAPY

Probably no group has done more to advance the field of physical therapy and hydrotherapy than spa physicians who utilize not only the better known physical therapeutic, electrotherapeutic and heliotherapeutic procedures as massage, diathermy and infra-red light but other hydrotherapeutic measures which they believe in as valuable therapeutic agents. No patient at any resort should ever be allowed to prescribe such procedures for himself. That is the specialized duty of the spa physician. The legitimate spa physician does not believe that a certain mineral bath is a panacea. He prescribes it rather as he would a drug, believing that a beneficial result will ensue if properly given. If a mineral water has value and is not a "cure all," it automatically follows that its use in therapeutics is limited and must therefore be given on medical prescription only. Any bath or treatment that can be taken indiscriminately is of no value. Similarly if the water has value and its use is indiscriminate it will do harm just as often as it will ever do good.

It is not my purpose here to enter into any discussion as to the use or value of the various mineral waters found at the various spas. While the value of such waters in certain disease states seems to be empirically proved, the scientific explanation for their action is still lacking. This applies to other physical therapeutic measures as well. Most physicians believe in the value of massage and yet it is difficult to measure quantitatively the beneficial effects of this universally recognized procedure. Empirically various peoples have received benefit from such treatments from the earliest days of Hippocrates and it is difficult to believe that any treatment which has stood such a test of time with ever increasing popularity is without some value. The severest critic of the use of mineral waters for treatment purposes however, has to admit three facts: (1) that such treatments, if properly prescribed can do no harm, (2) that there is a tremendous beneficial psychic effect on the patient following their use, (3) that the hour or more rest which the patient takes following such a procedure cannot help but be of benefit to him.

PSYCHIC ELEVATION OF MORALE

Most patients come to a spa in a hopeful expectant attitude ready to cooperate to the fullest extent and make a business of getting well. The spa should cultivate this attitude further. The isolation from the home and business environment the elimination of business worries and the depression incidental to nagging relatives with their many "don'ts" coupled with a change of environment new faces and the peace and relaxation which they find give a tremendous boost to their morale. In addition to this is the systematization of a daily routine with a definite schedule to follow prescribed for their own particular needs and a constant interest shown in their welfare. All this gives to the patient a psychic uplift which accounts in part for the tremendous success the spa has had in the past in the cure of various neuroses and functional disorders of the nervous system.

The health resort must offer to the patient the opportunity for recreation and entertainment. Nothing will sooner break down his morale than his own introspec-

tion. This is especially true of sufferers from functional neuroses, who thrive on the discussion of their own complaints thus ever keeping them alive. A bored patient is an uncooperative and dissatisfied patient. A good hostess can often be more valuable to a neurotic patient's morale than can any other form of treatment.

DEVELOPMENT OF A PHILOSOPHY

When as too often happens it is impossible to cure a patient entirely of a disease state so that the patient must carry on with a chronic disease process a proper outlook for that patient is of prime importance. To be able to accept these disabilities is important to the patient for his future happiness. The spa is often the buffer between a serious illness and the return of a patient to a limited life of usefulness in the economic plan. Let us consider as an example a man who has always been well. He has been a success in business and a power in his community. He is suddenly stricken with a coronary thrombosis. He spends a long period in bed either at home or in the hospital and then comes to the convalescent stage when he is getting back on his feet to a new life of narrowed activities and with it a depressed mental state because of his future incapacities. If during the convalescent period he goes to a health resort and gets in addition to proper medical care proper dietary, abundance of rest and proper exercise a knowledge of his physical reserve so that he knows exactly what he can and cannot do he still has not received enough for he must in addition develop a proper philosophy toward his incapacities. He must become reconciled to them, must accept them graciously, so that he can live happily in his new narrowed existence. He must learn to develop some hobby that will keep his mind active but save his heart. If the health resort does this and it should it has served a great purpose.

COMMENT

It is hoped that the foregoing discussion of features the modern health resort should and can offer the patient will be of interest to the physician. Such features offer the medical profession a unique and advantageous spot to which it can send certain types of patients. Because of its characteristics, the spa caters to a limited clientele. The ambulatory and chronically ill are candidates for its regimen. In addition the convalescent the fatigued and that great class of people who are well and wish to remain so can be benefited from its "cure." Any bedridden patient who is likely to remain so is far better off at the hospital or at home in his own bed for there is nothing miraculous about the "cure." It is simply a sane regimen of living wherein hygiene forms the keystone of treatment and physical methods supplant pharmacologic ones when by so doing the patient will be benefited.

There are resorts in this country ethically managed and ethically supervised, which offer to the patient the advantageous features here discussed. There are also resorts unfortunately which do not so qualify—resorts that depend on the exploitation of a mineral water of doubtful value the prescription of which is left to the whims of patients attracted by its unethical advertising.

How can the physician decide to which resort he can with confidence send his patient? A study of the advertising personal inspection and correspondence with its medical staff constitute the only means of so doing until such a time as the American Medical Association sees fit to adopt standards and classify these resorts as it does hospitals.

XANTHOMATOSIS (SCHULLER-CHRISTIAN'S DISEASE)

ROBERT A. STRONG, MD

NEW ORLEANS

While a wide diversity of opinion is reflected in an increasing literature the terms xanthomatosis and Schüller-Christian's disease are more frequently used to describe a syndrome which is beginning to follow a sufficiently typical course to justify its recognition as a disease entity. In all descriptions of this syndrome, three clinical features have been outstanding. They have been certain bony defects of the skull, diabetes insipidus and exophthalmos. Opinion seems to be quite unanimous that this clinical syndrome known today by various terms was first described by Hand¹ in 1893. He presented at that time the case of a 3 year old boy with exophthalmos and polyuria in whom an autopsy revealed a soft movable, yellow spot about 2.5 cm in diameter, involving the entire thickness of the skull in the right parietal region. He believed that it was due to tuberculosis. Kay² is credited with the second case in 1905. This was followed by reports of other cases by Pusey and Johnstone³ and Dietrich.⁴ Apparently nothing of consequence was reported until two years later when Schüller⁵ reported two cases, one in a boy aged 16 years with dystrophia adiposogenitalis, exophthalmos and marked cranial bone defects and the other in a girl aged 4 years with polyuria, exophthalmos and similar defects of the skull. Schüller felt that both of these cases were skeletal defects secondary to disease of the hypophysis cerebri. Three years later Christian⁶ reported a case showing similar defects in the bones, exophthalmos and diabetes insipidus and called attention to Schüller's case maintaining like Schüller, that the syndrome was due to a pituitary disturbance. In the years following many other cases of this syndrome were reported. In some of these reports many most interesting phases of the disease, together with theories of its etiology are discussed. Among the most interesting of them was

Fig. 1—Appearance of the patient showing degree of exophthalmos of the right eye.

one by Thompson, Keegan and Dunn,⁷ in which one of the earlier postmortem studies is reported. They suggested that the disease was due to infection and cited the work of Bailey and Bremer,⁸ and of Curtis,⁹ to support the contention that the symptom of polyuria was caused by an involvement of the hypothalamic region caused by pressure changes secondary to the cranial defects. In further support of this Denzer¹⁰ in 1926 called attention to the fact that in the chronological development of three symptomatic features of the syndrome in a case which he reported, the bony defects were primary and the exophthalmos and diabetes insipidus were secondary and not necessarily essential lesions. Since then analyses of series of cases not only confirm this but indicate that the bony defects are predominantly the initial symptom.

In the many reports, numerous terms have been used to describe the condition. The earlier authors spoke of it as Hand's disease and since then it has been spoken of as Schüller's disease, Christian's syndrome, and combinations of all three names. Extensive bibliographies have been attached to several of these articles, but without doubt the most elaborate contribution to our knowledge of the disease was made by Rowland¹¹ in 1928. He reviewed the literature extensively, presented two cases of his own and was the first to prove that Schüller-Christian's disease belonged in the same class with all the other diseases due to defective lipid metabolism. The term xanthomatosis was therefore suggested by Rowland to describe it and while all conditions due to disturbed lipid metabolism can be described under this term, there are several other names that have been retained for those not identical in their several manifestations to the original Schüller-Christian syndrome.

Five clinical entities have been included under the general heading of xanthomatosis by several writers. They are Gaucher's disease, Niemann-Pick's disease, Schüller-Christian's disease, the xanthomas occurring in uterine, diabetes and pregnancy, and the so called essential xanthomatosis. According to an analysis by Sosman¹² the first type, Gaucher's disease, involves chiefly the spleen, occurs at any age, but most frequently in female children, is familial and is fairly benign. Niemann-Pick's disease which has been spoken of sometimes as hepatosplenomegaly because of the marked enlargement of both the liver and the spleen is racial rather than familial occurring almost entirely in infants of the Jewish race, and is rapidly fatal. Schüller-Christian's disease occurs most frequently in children under 10 years of age, but by no means entirely, and is manifested by involvement of the bones of the skull and occasionally other bones, frequent evidence of diabetes insipidus, exophthalmos, occasional dwarfism, adiposogenital dystrophy and jaundice. It is neither racial nor familial and is fatal in about one third of the cases. The other two types show lipid deposits cutaneously, in tendon or tendon sheaths but have none of the other symptoms observed in the first three. These two are quite benign.

12. Sosman, M. C., Xanthomatosis (Schüller-Christian's Disease). Lipid Metabolism. J. A. M. A. 95: 110 (Jan. 9), 1932.

The etiology of this syndrome is unknown, but the etiologic factor common to all the members of the group is apparently a disturbance of lipid metabolism or of lipid excretion resulting in the storage of various forms of lipid material in the organs or tissues of the patient, either widespread and diffuse as in Niemann-Pick's and Gaucher's disease or localized in granulom-

Fig 2—Skull showing areas of decreased density about six weeks after roentgen therapy

atous deposits, as in the Schuller-Christian syndrome and the cutaneous xanthomas

According to Rowland,¹¹ a xanthoma was first described as a rare disease of the skin, and while it is still classed as a dermatologic condition he contends that it should be considered a systemic process with the skin and tendon sheath lesion as outward manifestations. Its chief characteristics macroscopically are the sulfur yellow to yellowish brown lesions and microscopically the large bright cells with vacuolated or foamy protoplasm in consequence of a high content of a fatlike substance. After numerous theories were advanced opinion seemed to have been crystallized that xanthoma may be considered as a variable symptom complex resulting from a disturbance of lipid metabolism and especially of cholesterol. As work progressed and information accumulated on the reticulo-endothelial system a new interest was aroused, according to Rowland in the xanthoma problem. Histopathologic studies suggested that the varied manifestations of xanthoma were not all in reality neoplasms of any organ or tissue but manifestations of the phagocytic action of the reticulo-endothelial system. The xanthoma cell is a cell of reticulo-endothelial origin infiltrated with lipoids and the reticulo-endothelial system is said either to remove an excess of lipoids from the tissues or to store an excess in areas in which trauma or infections may have stimulated a collection of histiocytes.

Apparently then in the light of our present limited knowledge much of which may be found in Rowland's paper¹¹ analyzing these several clinical syndromes xanthomatosis may be regarded as being a clinical disease due to a disturbed lipid metabolism which is not necessarily related to the general metabolism of fats but is in a large measure influenced by the part played by the reticulo-endothelial system. According to Rowland's interpretation of the process lipid and other substances when in excess in the body fluids become pathogenic to the individual. There is at first an irri-

tation of the vessel walls, then perivascular cell infiltration takes place, the lesions increasing as a result of the progressive blockage of the reticulo-endothelial system. In each of the conditions that have been previously enumerated under the general head of xanthomatosis there is a difference in the clinical form in the pathologic structure of the lesions and in the nature of the lipoids concerned but Rowland believes that they all represent the same irritative proliferation of connective tissue elements or reticulo-endothelial hyperplasia. They are all manifestations of the same pathologic process but are probably modified by certain differences in the individual patient's general metabolic state. He thinks that the bone destruction exophthalmos diabetes insipidus dwarfism and infantilism often present and frequently regarded as evidence of disturbed pituitary function are the results of this pathologic state.

The case that I report seems to fall quite definitely into the class of the Schuller-Christian syndrome of xanthomatosis.

REPORT OF CASE

J. T., a white boy aged 6 years, was admitted chiefly for protrusion of the right eye. About three years before the patient fell against the rocker of a chair, striking the left side of his head. This caused a swelling which was peculiar in that at times it would appear and then disappear. The father stated that about one year later he noted a slight protrusion of the right eye, which was downward and forward. At no time did the child complain of any symptoms except an occasional headache. He was first seen about six months after the father observed the protruding eye, because it was growing worse. The child never complained of pain in this eye and the vision

Fig 3—Anteroposterior view of skull illustrating decreased density to the right of orbit showing exophthalmos

was never impaired. About the time that the eye protruded the patient began losing some of his teeth. They became loose and were easily extracted.

There was nothing remarkable about the past history and the only disease of childhood that the patient had had was whooping cough. He had never had orange juice or any of the conventional sources of vitamin D as an infant. In a like manner there was nothing remarkable about the family history of the child. As far as could be determined the patient had

never been exposed to tuberculosis and there was no history of neoplasms or syphilitic disease in the family. The father was 30 years old and was in good health. The mother was 27 years old and lately had been said to be suffering from kidney trouble. The patient had three brothers aged 11 years, 3 years, and 2 months and one sister aged 9 years. All of them were in good health. The family lived in a rural community under fairly good conditions.

When first seen the child appeared to be perfectly well. He was of a quiet disposition and talked very little. He understood all the questions that were asked him and his answers

Fig. 4—Frequency of symptoms in Schüller-Christian's disease—Sundelius

were quite prompt and intelligent. He was very cooperative when he was being examined. He was an ambulatory patient and was able to eat a regular diet and play around the ward with the other boys of his age.

The cranium was fairly well shaped. The hair was thin and soft to touch, and there were no lesions or scars. There were no marked protuberances or depressions, and there was no pain on palpation anywhere on the skull. When the child was first seen by Dr. Mims Gage of the department of surgery, he found very definite soft spots, which could be elicited on careful palpation of the skull in positions which later proved to be areas of decreased density to the X-rays. These irregular defects were rather widespread in lateral and anteroposterior roentgenograms of the skull. They were especially well defined in both frontal regions, the right orbital roof and the occipital region. The original plates unfortunately are not available but some of these areas are still shown in lateral and anteroposterior views of the skull of this child which were taken several months after roentgen therapy. They have shown some improvement but can still be seen.

The child's vision seemed to be perfect but the right eye showed a marked degree of exophthalmos. It was about 2 cm. below the left; its defect is shown in figure 1. He could not be made to say that the eye hurt and there were no inflammatory changes in the conjunctiva nor was there any purulent discharge. There was some increased lacrimation in the defective eye occasionally. The pupils of the two eyes were equal and responded to light and in accommodation. There were no opacities of the cornea and no edema or swelling of the eyelids. No pain could be elicited on palpation of either eyeball. Notwithstanding the downward and forward protrusion of the right one the eyebrows of the two eyes were on the same level.

There was no excessive thirst, nocturia, polyuria, hematuria or pyuria. A complete examination of all other organs revealed nothing pathologic or abnormal.

Several roentgenograms of the head were made and revealed the bony defects. This supplied the second pathognomonic sign of the triad by which Schüller-Christian's disease is recognized. The long bones, pelvis and chest showed no roentgenologic evidence of bone changes at any time.

Six roentgen treatments were given over a period of three months following the date when the patient was first examined, and X-ray studies made at intervals of about six or seven months following treatment showed some improvement in the areas of decreased density in the skull (figs. 2 and 3).

Following Rowland's practice the patient was put on a very low fat diet and the calories were made up with carbohydrate. Because of the satisfactory results that have been obtained with the banana diet in celiac disease and other conditions in

which there is an inability properly to utilize fats the surgical consultant Dr. Mims Gage, suggested that a considerable part of this carbohydrate should be supplied in the form of ripe bananas.

At no time since the patient has been under observation has there been any evidence of diabetes insipidus. There has been gradual improvement in the bony defects of the skull shown in the frontal region in the lateral roentgenograms but the defect in the parietal bone has remained unchanged to any marked degree. There has been little if any improvement in the exophthalmos.

Several blood pictures have been made of which the following is representative: red blood cells 4,200,000; white blood cells 5,750; hemoglobin 75 per cent; small mononuclears 34 per cent; large mononuclears 5 per cent; eosinophils 1 per cent; neutrophils 60 per cent.

The urine was not remarkable. It was clear and had a specific gravity of 1.024, the reaction was alkaline and there was no albumin, sugar or bile. The sediment revealed nothing abnormal. The blood chemistry varied little from the following: nonprotein nitrogen 29 mg. per hundred cubic centimeters of blood; urea nitrogen 14 mg.; creatinine 1.2 mg.; blood sugar 63 mg.; cholesterol 49 mg.

COMMENT

The diagnosis in this case was obviously the Schüller-Christian type of xanthomatosis and confirms the frequently expressed opinion that there may be some variety in the signs and symptoms of any given case. In this instance only two of the triad of symptoms were present, because the child has never developed any evidence of diabetes insipidus. This may be explained by the fact that there are probably no lipid granulomas situated so that they would affect the region of the tuber cinereum or the posterior lobe of the hypophysis. Another positive finding was a more than ordinary loosening of the teeth which is listed as one of the chief symptoms and is believed to be due to destructive processes in the superior and inferior maxilla. The blood cholesterol in this case was 40 mg. per hundred cubic centimeters of blood and if the upper normal of the total blood cholesterol is considered to be 230 and the minimum 100 it will be seen that there was no hypercholesterolemia. Rowland, however, has invited attention to the fact that the cholesterol need not be increased.

Fig. 5—Age incidence in Schüller-Christian's disease in 134 cases collected from the literature by Jankovsky.

From a review of the literature the impression is gained that there may be any combination of the signs and symptoms with any chronological appearance. It will be noted in this history that the child was struck on the left side of the head when he fell against the rocker of a chair but that the exophthalmos which appeared one year later was in the right eye. Again there is adequate evidence in the literature to indicate that while symptoms may be initiated by trauma or infection they have appeared without either.

Sundelius¹³ has just made a most careful review of the literature and was able to collect information on eighty cases. In sixty-three of these he was able to tabulate the frequency with which various symptoms were encountered. The graph shown in figure 4 was prepared from the figures that he collected. At the time of his review forty-two patients were alive and twenty-one were dead. He was able to determine the sex in only fifty-six of the patients, forty-one were male and fifteen were female. Initial symptoms were traceable in fifty-seven cases and they occurred in the order of frequency shown in the accompanying table.

Dauksys,¹⁴ who tabulated the literature in reporting a case of his own, contends that it is his impression that 123 cases had previously been reported. Seventy-eight of these were males and forty-one were females and in the five others the sex was not mentioned. Almost half of the cases (fifty-nine of the 124) are reported in children under 6 years of age, and two thirds of them in children of 12 years or under. The maximum number of cases was in the second, third and fourth years. The age incidence at the appearance of the first symptom in the 124 cases collected by Dauksys is shown in the graph in figure 5. Beyond the first decade of life the age distribution was fairly general, except in the third decade in which he found

Initial Symptoms in Fifty Seven Cases

| | |
|-------------------------|----|
| Defects of skull | 20 |
| Diabetes insipidus | 14 |
| Loosening of teeth | 9 |
| Gingivitis | 9 |
| Cutaneous xanthomatosis | 6 |
| Arrest of growth | 3 |
| Splenomegaly | 2 |
| Jaundice | 2 |
| Symptoms in the femur | 2 |
| Exophthalmos | 1 |

fifteen of the cases grouped. The blood cholesterol ranged from 525 down to 120 mg per hundred cubic centimeters.

Because of the fact that roentgenology and diet seem to hold out more therapeutic encouragement they were the only two measures used in this case and while it can be said that there has been some improvement in the bony defects of the skull the exophthalmos has not changed to any appreciable degree. No conclusive evidence has appeared to indicate that the administration of endocrine extracts offers any hope of influencing the metabolism of fats or the pituitary secretion.

SUMMARY

1 From the collected literature as well as from observation of the course in this case the impression is gained that Rowland has offered the most plausible explanation of the syndrome which is most frequently referred to as the Schüller-Christian type of xanthomatosis. Until proved otherwise it must be considered to be due to a disturbance of lipid metabolism with an occasional but constant increase in blood cholesterol and a subsequent deposition of lipoids chiefly in the form of cholesterol or its esters in various organs and tissues of the body as well as in the reticulo-endothelial system. Local trauma or infections may determine the location of the deposition of lipid material but apparently neither is necessary.

2 The three characteristic clinical symptoms are bony defects of the skull diabetes insipidus and exophthalmos. The symptoms less frequently encountered

are gingivitis, dwarfism, bone defects of the skeleton other than the skull and occasional adiposogenital dystrophy. A diagnosis of the condition may be made in the absence of one or more of these symptoms, but defects in the skull should be made an indispensable condition for the diagnosis of Schüller-Christian's disease.

3 The most hopeful treatment for this condition is through diet and roentgen therapy applied to the areas of lipid deposit. This apparently benefits the bone defects but does not improve the exophthalmos.

1430 Tulane Avenue

ABSTRACT OF DISCUSSION

DR H. R. WAHL, Kansas City, Mo. The use of the term 'xanthomatosis' in the title of this paper is confusing. It is apt to be regarded as synonymous with Schüller-Christian's disease when in reality it is a broad term including a wide variety of lesions characterized by an abnormal accumulation of lipid substances. Schüller-Christian's disease is similar to Gaucher's disease and Niemann-Pick's disease in that it represents an accumulation of lipid substances in the reticulo-endothelial system but differs in the type of lipid substance deposited. In Gaucher's disease the lipid is a cerasin, in Niemann-Pick's disease it is a lecithin while in Schüller-Christian's disease it is a cholesterol compound. The concept that xanthomatosis is a metabolic disturbance of lipids with involvement of the reticulo-endothelial system is based on two assumptions neither of which has been proved. The first is that the xanthoma cell is derived from the reticulo-endothelial system. This apparently is true of the three diseases just mentioned but there is much difference of opinion in the nature of the cell in other forms of xanthomatosis, for example xanthomatous deposits in giant cell growths of tendon sheaths. In the second place it assumes that there is chemical evidence of a metabolic disturbance such as hypercholesteremia when the fact is that in most instances such a change cannot be demonstrated. It may be absent even in Schüller-Christian's disease. Moreover xanthomatous deposits are not more frequent in cases in which there is a high blood cholesterol, for example, pregnancy and chronic jaundice. The essential diagnostic feature is the demonstration of lipid deposits (biopsy) in various bones especially of the skull. Other symptoms are usually referable to the location of these deposits, for example exophthalmos and diabetes insipidus. These lipid deposits should be confirmed by suitable lipid stains. Chronic osteitis cystica may resemble this disease but can be eliminated by the evidences of normal phosphorus and calcium metabolism. I am wondering whether the phosphorus and calcium content of the blood was determined in this case. There is another disease that may be confused with Schüller-Christian's disease especially if the latter shows no cholesteremia and that is malignancy with metastasis to bones and skull. Recently such a case in a young child was diagnosed Schüller-Christian's disease but the autopsy revealed a neuroblastoma arising in the celiac plexus and sympathetic trunk with extensive metastasis to the bones and to the skull with exophthalmos.

DR JOHN ZATORSKY, St. Louis. Dr. Strong has done good service in bringing the subject of xanthomatosis before us. Sometimes an intensive study of a rare disease brings out new and important facts. This is a rare disease. In the forty years of my practice I have seen only one case in which I thought this particular triad was present. I have diagnosed two cases of Gaucher's disease one of which was proved to be such by the finding of characteristic cells after removal of the spleen. I was interested in Rowland's intensive study. All his work as well as some recent papers seem to me to have confused the subject very much. These authors have tried to bring all these diseases under the term of reticulo-endotheliosis but this was objected to because a reticulo-endotheliosis is found in many infectious diseases. A recent textbook has these diseases grouped under the name of lipid disturbances and yet a lipid disturbance has not been proved in many of the cases. Consequently we pediatricians are very much confused in the interpretation of this disease. We have been still more confused

¹³ Sundelius, Harald. The Lipoidosis, with Special regard to The Schüller-Christian Type. Acta Med. Scand. 57: 40, 1936.

¹⁴ Dauksys, Joseph. Xanthomatosis. Schüller-Christian's Disease. Missouri Med. J. 32: 40 (Dec.) 1937.

recently by a paper, by Abt and Denenholz, describing the so called Letterer-Siwe's disease, in which a tremendous hyperplasia of the macrophages was demonstrable in the spleen, bones and other organs, but the cells did not contain lipid substances. In the past we have been diagnosing some of these cases as chloroma, and some of them as Banti's disease. I met a similar syndrome years ago in a case which I diagnosed as multiple myeloma. This subject has no great practical clinical importance. It remains for the research men, the histologist and the chemist, to dig us out of this terrible confusion.

DR. ROBERT A. STRONG, New Orleans. Because of the lateness of the hour I have stated only a small part of what was in this paper, and if it is published a considerable number of the points brought out in the discussion will be answered. I realize that this is an unusual and rather rare disease. For that matter, so is erythroblastic anemia. It is scarcely 9 years old. We don't know anything about it, but that is no reason why we should not try to find out something about it. If these cases were brought to our attention, we would probably know more about the disease than we know now. The differential points in the various types of xanthomatosis have been brought out and analyzed in the paper. There are Wilson's disease, erythroblastic anemia, xanthem subitum and several other unusual diseases about which we would like to know more. Concerning the practical value, after all we are in the business of saving children, and children die from these unusual things as well as they do from appendicitis, about which we have heard so much this afternoon.

LYMPHOBLASTOMA OF THE STOMACH

REPORT OF CASE, WITH ESPECIAL REFERENCE
TO THE GASTROSCOPIC APPEARANCE

JOHN F. RENSHAW, M.D.
LOS ANGELES

The gastroscopic appearance of lymphoblastoma of the stomach seems to have been observed in only two cases.¹ The case to be described in this report not only is the third of this type to be recorded but also presents several noteworthy features.

REPORT OF CASE

Mrs. L. L., aged 51, a housewife, seen first Nov. 3, 1932, by Dr. Alexander Brunschwig, complained of a swelling in the neck, of loss of weight and of shortness of breath. The "swelling" in the neck had been discovered two years previously by a physician who was treating the patient for "gallbladder" trouble. The diagnosis was based apparently on an attack of epigastric pain which "doubled her up," nausea and a pale and sallow skin, although definite jaundice had not been present. The painless swelling in the neck had remained about the same size during the two years the physician had had the patient under observation. There had been a loss of 20 pounds (9 Kg.) in one and one-half years, although the appetite had remained fairly good. The shortness of breath on mild exertion had been noted for two months.

The past history and system inquiry were negative except for tonsillectomy in May 1932 for salivation which had given only slight temporary improvement. There was no history of carcinoma in the family.

The patient was fairly well nourished. There was nothing unusual about the skull, eyes, nose or ears. The tongue was large. The papillae at the base of the tongue were enlarged and inflamed. The sublingual veins were engorged and cyanotic. The sublingual glands were prominent. Below the midportion of the mandible on the left side there was a firm swelling about 4.5 cm. in diameter. It was not tender and the overlying skin was freely movable. The neighboring glands were

not palpated, nor were the epitrochlear and inguinal glands. The thyroid was normal on palpation. The percussed area of cardiac dullness was normal and the tones were clear. The pulse was 80 per minute. The lungs were normal. The abdomen was soft. No abnormal masses were palpated. A rectopelvic examination was not made. The extremities and reflexes were normal.

Blood examination revealed erythrocytes 5,000,000, hemoglobin (Sahl) 94 per cent, leukocytes 10,100, with 87 per cent polymorphonuclear leukocytes, 6 per cent large lymphocytes, 3 per cent small lymphocytes, and 4 per cent mononuclear lymphocytes. This blood study was repeated two days later with a similar result. The blood Wassermann and Kahn tests were negative. The urine was normal. A roentgenogram of the chest revealed no evidence of enlargement of the mediastinal glands. November 4 a group of firm, discrete cervical lymph glands was easily excised with the submaxillary gland in toto. Microscopic examination disclosed that the normal architecture was largely destroyed, although a few remnants of germinal centers could be seen. Under low power the nodes were uniformly cellular, with definite invasion of the capsule (fig. 1). The cells appeared uniform in size and had a rounded nucleus with a dense chromatin network and a small amount of cytoplasm. There was no eosinophilic infiltration or fibrosis. No mitotic figures were seen (fig. 2).

Radiation therapy was given for three successive days, the daily dose being 393 roentgens measured in air, through a 15 by 15 cm. portal covering the lateral surface of the neck. Following this the patient felt quite well, gained 5 pounds (2.3 Kg.) in the first month and had no evidence of recurrence until twenty months later (Aug. 29, 1934), when the shortness of breath recurred. A roentgenogram of the chest revealed questionable evidence of mediastinal lymphadenopathy. Additional radiation therapy was given, the daily dose being 306 roentgens through a 20 by 20 cm. anterior chest portal for three days followed two months later by 314 roentgens daily for three days through a 15 by 15 cm. posterior chest portal. Following this course of irradiation the patient was completely relieved of the shortness of breath. Roentgenograms of the chest revealed no evidence of mediastinal lymphadenopathy.

Sixteen and one-half months later, Jan. 14, 1936, the patient reappeared and complained of epigastric pain of one month's duration. A severe pain had appeared suddenly beginning

Fig. 1—Section of cervical lymph gland. Normal architecture is largely destroyed by lymphoblastoma. Delimited penetration of capsule. Red cell from a photomicrograph with a magnification of 120 diameters.

under both costal margins and radiating toward the umbilicus. It had lasted several hours and then persisted as a dull pain and soreness with a sensation of epigastric fullness. Physical examination revealed no lymphadenopathy. There was marked epigastric tenderness, but no masses were palpated. Blood studies were repeated revealing erythrocytes 4,300,000, hemoglobin 144 Gm. (Newcomer), leukocytes 6,800 with 68 per cent polymorphonuclears, 14 per cent small lymphocytes, 6 per cent monocytes, 3 per cent basophils and 9 per cent eosinophils. Roentgen examination revealed faint visualization of the gall bladder after oral administration of the dye. The esophagus and duodenum were normal roentgenologically, but the gastric rugae were markedly enlarged and could not be obliterated by

1. Schindler, Rudolf. Die gastroscopische Diagnose des diffusen Lymphosarkoms des Magens. *Klin. Wchnschr.* 1: 2046 (Oct. 14) 1922. Thirty Cases of Neoplasms. *Arch. Int. Med.* 32: 635 (Oct.) 1923. Leberbuch und Atlas der Gastroscopie. Leipzig: Lehman, 1923. Moutier, F. Traité de gastroscopie et de pathologie endoscopique de l'estomac. Paris: Masson & Cie, 1913.

pressure. The conclusion was reached that the appearance was due to a marked submucosal infiltration which had not broken through the mucosa, but from the x-ray examination alone it was not possible to differentiate definitely between a marked hypertrophic gastritis, a submucosal infiltrating carcinoma and in view of the biopsy an infiltrating lymphoblastoma (fig 3).

Gastroscope with the Wolf-Schindler flexible gastroscope² was performed with ease January 17 all parts of the stomach

The gastroscopic appearance was spectacularly changed. The stomach was almost normal. The angulus was smooth and the large nodes and ulcers had disappeared. A few small nodes persisted in the lesser curvature but all other parts were normal. Dr Rudolf Schindler also observed both gastroscopic examinations and concurred in the observations and diagnosis.

COMMENT

This case of lymphoblastoma of the stomach presents several noteworthy features. It is the third case of this type to be observed gastroscopically and reported.

Two types of lymphoblastoma of the stomach have been observed gastroscopically. The first two cases reported (Schindler and Moutier) were diffuse infiltrating processes involving the whole stomach. This case was circumscribed.

Schindler's patient was a woman aged 60, who complained of epigastric pain, vomiting, anorexia and weakness. Physical examination was negative. The blood, urine and stools were all normal. There was no free hydrochloric acid with the Ewald test meal. Roentgen examination of the stomach was reported negative. The gastroscopic appearance, however, was striking. The entire mucous membrane was soft and loose. It was covered with a large number of mucous patches and contained unusual mucosal hemorrhages, many of which formed hemorrhagic vesicles and bullae. Many folds throughout the stomach were thickened, rigid, and studded with nodules. Postmortem examination four months later confirmed the diagnosis of lymphoblas-

Fig 2—Section from figure 1. Tumor cells are seen in and on both sides of the capsule. Reduced from a photomicrograph with a magnification of 1,160 diameters.

being well seen except the lesser curvature of the antrum. The region of the angulus contained marked changes (fig 4). The angulus was a scalloped nodular curve with a whitish ulceration toward the posterior wall. The musculus sphincter antri was cordlike and nodular. It contained a greenish gray linear ulceration about 2 cm long and 3 mm wide. There was a small hemorrhagic spot on the greater curvature of the antrum in a swollen mucous membrane without folds or nodes. In the lesser curvature of the body just above the angulus there were many large nodes. These extended over the posterior wall of the lower third of the body. The upper parts of the posterior wall were normal as was the entire anterior wall which showed the normal delicate network of folds. The entire mucous membrane was the usual glistening orange red. The surface of the tumor was not smooth but irregular and cauliflower-like yet not definitely papillomatous.

Radiation therapy for the stomach was given 200 roentgens daily through a 20 by 20 cm epigastric portal for five treatments and 200 roentgens daily for three treatments through a lower thoracic upper lumbar portal. One month later February 14 the roentgen examination of the stomach revealed marked improvement. During fluoroscopic examination the stomach appeared normal except for slightly enlarged rugae which however were pliable and could be obliterated with slight pressure. The roentgen film (fig 3) revealed mottled rugae in the upper parts of the stomach and several folds radiating from a point near the angulus. No ulcer crater was demonstrated.

Fig 3—Before treatment: a, no evidence of abnormal contour in filled stomach; b, marked filling defect and thick rugae in filled stomach with compression technique; c, thick folds demonstrated by mucosal relief with a single swallow of barium sulfate. One month after treatment: d, smaller folds and radiation of folds from a point near the angulus.

toma of the entire stomach. Schindler believes that the appearance of the diffuse infiltrating process is characteristic and cannot be mistaken for anything else.

Moutier describes his case as an infiltration of the antrum, lesser curvature and anterior wall. The color was dark or brown red. There were many nodules

² Schindler, Rudolf. Gastroscope with a Flexible Gastroscope. *Am J Digest Dis & Nutrition* 11: 656 (Feb.) 1946.

and erosions and hemorrhagic ulcerations. The mucosa was friable and bled at the slightest trauma. Unfortunately, he omitted a statement of how the gastroscopic diagnosis was confirmed.

In contrast to the diffuse type the circumscript lymphoblastoma is less characteristic.

The differential diagnosis of the gastric lesion of the case reviewed in this report would have been more difficult had there not been a cervical biopsy. The gastroscopic appearance was not characteristic, and the other methods of diagnosis had been of little value. Stool, blood, urine and gastric studies were negative. Roentgen examination of the stomach by means of mucosal relief methods was of little aid. It was not possible to differentiate definitely lymphoblastoma from carcinoma, severe hypertrophic gastritis, granulomas or other submucosal infiltration which had not broken the mucous membrane. Any of these infiltrating lesions cause stiffening of the gastric wall and enlarged rigid rugae.

Fig. 4—Gastroscopic appearance before treatment. Marked nodular infiltration (a) two ulcers (b, b) mucosal hemorrhage in greater curvature of antrum (c) position of gastroscopic objective (d)

Without the knowledge of the cervical biopsy and the response to radiation therapy the diagnosis of lymphoblastoma of the stomach would not have been made. This case was a localized nodular process in contrast to the widespread hemorrhagic, nodular infiltration in Schindler's case. This case appeared more like adenocarcinoma. Yet it would be unusual to find such smooth well demarcated ulcers in such a large carcinomatous mass. The carcinomatous ulcer is either a superficial extensive necrosis or a deep crater with a rough base and poorly defined margins. There is more color change as a rule in carcinoma with ulcerations. The dramatic response to radiation therapy, which was inadequate for carcinoma substantiates the statement that this was not carcinoma. A severe hypertrophic gastritis has never been described with the appearance of this case. A severe gastritis is more diffuse and the nodes are never as large as in this case, even in "pseudopolypoid" hypertrophic gastritis. The cases of syphilis observed have had no constant characteristics. There have been tumors with and without ulcers. A positive blood serum reaction is the only definite differential point. In this case the Wassermann and Kahn tests were negative. Tuberculosis of the stomach presents at postmortem irregular ulcers with nodular bases and margins, sometimes with tumor formation. Tuberculosis of the stomach has not been observed gastroscopically. Other granulomas have not been observed.

From the standpoint of therapy and prognosis the differential diagnosis is important. Every means of diagnosis should be employed. Gastroscopy is a definite aid in the diffuse infiltrating form of lymphoblas-

toma. In the circumscript form gastroscopy may be of value if an alert gastroscopist considers the possibility of lymphoblastoma when the gastroscopic appearance is not "typical" of other conditions. Gastroresection was not done in this case because of the previous involvement of the cervical and mediastinal lymph glands and the excellent result from the radiation therapy. Gastroscopy may be of value in the future when dealing with possible recurrences and in evaluating the effect of therapy.

Clinical Notes, Suggestions and New Instruments

GLOMUS TUMOR ARTERIAL ANGIO-NEUROMA OF MASSON

H. N. COLE, M.D. AND W. E. SROUB, M.D. CLEVELAND

Mrs. J. S., aged 33, a patient of Dr. Sroub's complained of a persistently painful little finger of the left hand Nov. 8, 1933. She stated that seven years before the tip of this finger began to be tender and that this had increased to the present time. It was at this time so exquisitely painful that she could get no relief, day or night. The pain traveled up her arm to the shoulder. She was constantly shielding the finger. There was no history of previous trauma. The nail had been trimmed by Dr. Sroub. Roentgenograms showed nothing. All local measures had been in vain. The patient was frantic.

Physical examination showed a blood pressure of 200 systolic, 110 diastolic, with the left border of the heart in the nipple line. The second aortic sound was accentuated. A roentgenogram showed no cervical rib. Otherwise the general physical examination was negative.

The outer aspect of the nail of the little finger of the left hand showed an area with a faint reddish blue color under the nail and extending out on the soft parts. The area was exquisitely tender to the lightest palpation. There was a suggestion of atrophy of the digit as compared to the right.

Microscopic section from tumor. A, vascular spaces with flat endothelial cells; B, large epithelioid cells with reniform nuclei; C, mucoid neural elements.

Having in mind the complete review and report of Kohn¹ and Mayer² and the report of Lewis and Geckler³ of their experience at Johns Hopkins we made a diagnosis of probable

From the Department of Dermatology and Syphilology of the Western Reserve University School of Medicine.
¹ Kohn, Victor, and Mayer, J. R., *Tumor of the Nail*, *Ann. Surg.* 1934, 100: 111 (June), 123.
² Lewis, Dean, and Geckler, C. F., *Clinical Medicine*, 1934, 105: 775 (Sept. 7), 193.
³ Lewis, Dean, and Geckler, C. F., *Clinical Medicine*, 1934, 105: 775 (Sept. 7), 193.

glomus tumor This was based on its location under the nail on its long duration and on its exquisite tenderness

Under gas ether anesthesia the nail was removed by Dr Sroub and an incision was made along the outer border down to the subcutaneous tissues When these were laid back a small sharply defined, apparently encapsulated, somewhat elongated bluish tumor 1 by 0.5 cm was found The tumor, with the surrounding tissues, was excised in its entirety, fixed in solution of formaldehyde, run through paraffin and cut

A section stained with hematoxylin and eosin revealed a normal epidermis, corium and subcutaneous tissue. In the extreme depth of the section at one end was a fibrous encapsulated portion showing many long vascular spaces lined with flat endothelial cells Outside these spaces were numerous cells with pale staining reticular-like protoplasm containing a deeper stained oblong nucleus—epithelioid cells Scattered freely in between these cells were numerous mucoid like areas representing neural elements of the glomus

COMMENTS

Report is made of a long standing glomus tumor involving a little finger Barre and Masson,³ with special staining methods, concluded that these tumors are benign outgrowths of a structure normally present in the skin and subcutaneous tissue of the whole body The glomus bodies through their neurogenous components, act as regulators of the blood supply of the capillaries and arterials of the skin and thus indirectly regulate skin temperature The tumors are hardly more than enlargements of the normal glomus and are benign

In differential diagnosis one might think of a subungual papilloma, of a subungual fibroma, of a ganglion, of a melanotic whitlow of Jonathan Hutchinson, and finally of a glomus tumor A melanoblastoma would develop more rapidly Moreover, histologic study would tell the story The long duration of a lesion, its increasing painfulness and tenderness, and yet its apparent benign character, the underlying light bluish color of the area all should lead one to suspect a glomus tumor This patient within two days after the operation, experienced complete relief from all symptoms We now feel that with better knowledge of this condition it will be found to be far from a rare entity

CONTACT DERMATITIS FROM MENSTRUAL PAD

FRANK E. CORMIA M.D. MONTREAL

Psychogenic factors until recently¹ have been given a position of shifting importance in the causation of certain lesions of the skin Kriebich² has stated that many cases diagnosed as contact dermatitis are in reality examples of neurodermatitis with local precipitating factors In a recent case this concept has been strikingly illustrated and will be briefly considered

REPORT OF CASE

History—A generally healthy white Canadian woman, aged 35, a widow, seen in my office Nov 29, 1935 presented an acute sharply margined dermatitis limited to the genital region and adjacent surfaces of the thighs and lower part of the abdomen

Six days previously she first experienced a generalized pruritus, which rapidly became severe being especially pronounced in the genital region Two days later one day before the termination of the last menstruation an acute erythema developed on both labia majora the anterior aspect of the perineum the inner aspect of the groins and the adjacent surfaces of the thighs in a fanlike distribution the mons veneris and the adjacent surface of the lower part of the abdomen The eruption rapidly became elevated owing to an in situ edema, but no macroscopic vesiculation was seen There was an accompanying intense pruritus and burning The area of dermatitis corresponded almost exactly with that covered by the menstrual pad except that the posterior portion of the perineum and the lower inner aspects of the buttocks were spared

The general physical examination revealed only a grade 1 ichthyosis and a mild dermatophytosis in the toe webs There was no history of dietary indiscretion, drug ingestion or use of irritating soaps She did not take douches

Of significant interest, however, was the fact that for some years the patient had been under a severe nervous strain, engendered on the one hand by a markedly restricted budget and consequent financial worries and on the other by the home environment, she and her two children being compelled to live with a sister with whom she was constantly engaged in domestic altercations It is noteworthy too that she was an aggressive and irritable type, with some degree of sexual repression About ten days before the onset of the dermatitis, she underwent the severe mental shock of being unsuccessful in an attempt to obtain a more lucrative position which would have made her financially independent It was during this period of anxiety and acute depression that the generalized pruritus and subsequent dermatitis appeared

The past history included typhoid at 10 years and scarlatina at 30 About one year before the present trouble a markedly pruritic circumoral dermatitis developed The lesions were acutely erythematous, with some edema, and residual lichenification and scale The dermatitis appeared in three attacks, each lasting about five days The onset of each attack corresponded with that of the menstrual period, although a definite endocrine causation could not be found (It is of interest to note here that since the involution of the present trouble there has been a recurrence of the dermatitis this time in the intermenstrual period The only significant associations accompanying all four attacks have been periods of worry and nervous depression) The past and family history was otherwise irrelevant

Contact Incitation—On the day following the onset of the dermatitis in the genital regions, patch tests were done on the forearm flexures with Lux laundry flakes, dilute household ammonia, house water, house dust, cat fur, rayon and woolen bloomers, flannel and silk nightgowns, outer gauze, intermediate and inner cellulose layers of the menstrual 'Kotex' pad, and a control During and after the application (and handling) of the test materials, the patient complained of increasing pruritus and erythema in the lesions The patches were removed after twenty-four hours and no reactions were observed but four hours later the sites of application of both the intermediate and the central layers of the menstrual pad became pruritic and erythematous Vesiculation did not appear but the redness persisted for several days The remainder of the patch tests were negative

Two months after the involution of the eruption (the dermatitis subsided rapidly with soothing local and autohemotherapy), the patient was again tested with the two layers of the menstrual pad to which she had previously reacted The results were interesting Positive erythematous reactions were obtained on the forearm as before, with both intermediate and central layers of the "Kotex" pad There were no reactions in the areas of previous dermatitis

A few days after the completion of this investigation and following a bitter quarrel with her sister the patient developed acute erythema nodosum-like lesions with large surrounding erysipelatous flares on the upper inner aspects of both legs These persisted for about two weeks and were definitely aggravated during three separate periods of nervous stress The fact that fungi were demonstrated from a mild dermatophytosis of the toe webs and that the lesions disappeared two days after treatment of this focus with Whitfield's ointment suggested that the lesions were of the dermatophytid type.³ However a local trichophyton test gave only a delayed response without the development of actual nodose lesions and this supposition could not be definitely verified No foci of infection were evident and the tuberculin test was negative

COMMENT

This patient presented, successively an acute circumoral neurodermatitis, a contact dermatitis from the menstrual pad, and erythema nodosum-like and erysipelatous lesions on the legs A common factor of high tension and nervous shock accompanied all three eruptions

The menstrual pad dermatitis is apparently a dermatologic rarity since a search through the literature did not reveal a

similar instance. Dr Lloyd Arnold of Chicago⁴ reported that he had heard of a single, although unproved case. Two other patients developed urticaria after the use of "Kotex" pads, but no causal connection was proved. The author has observed, in a case of urticaria due to house dust the rapid appearance of large urticarial lesions (in the contact area) following the application of the menstrual pad. These lesions were observed with two standard types of pad. It is possible that the dust antigen contained sufficient cellulose particles to account for the contact reaction. Dr Arnold also kindly submitted the following information in regard to the manufacture of "Kotex": "Kotex" wadding is pure cellulose. The whole process is for the removing of all other substances, organic and inorganic. There is no foreign material of any kind added to this cellulose."

The mild dryness of the skin was apparently unrelated to the rapidly developing generalized pruritus which was seemingly of neurogenous rather than endocrine (premenstrual pruritus) origin. It is noteworthy that the patient had previously worn the same type of menstrual pad for years again confirming the well known fact that local cellular sensitization may not occur until after many years of intimate contact. The paucity of irritating effects from the use of "Kotex,"⁵ plus the fact that the patient exhibited only a delayed erythematous reaction to the patch test performed at a distant site, suggests that the sensitivity was of low grade. The association of the dermatitis with a period of emotional and nervous shock pointed to a lowered cutaneous threshold to the previously innocuous contact due to an increased protoplasmic irritability thus allowing development of the dermatitis. The negative reaction to the patch test in the area of previous dermatitis was probably the result of a prolonged refractory period.

SUMMARY

In a proved case of contact dermatitis from "Kotex" pads the dermatitis was apparently precipitated by nervous shock, with an underlying contact factor.

2068 Sherbrooke Street West

SOME DIFFICULTIES ARISING IN THE USE OF PROTAMINE INSULINATE

FREDERICK M. ALLEN, M.D., NEW YORK

Observations which I have been enabled to make¹ have corroborated the delayed action and the clinical benefits in suitable cases of diabetes as reported by the first writers on protamine insulinate.² Since this new compound was devised particularly with a view to a better control of the severe and difficult forms, the cases for my first trials were selected chiefly from this class. The tentative conclusion formed up to the present time is that some such cases, characterized by the most labile and fluctuating blood sugar, offer special difficulties for the new treatment. The following summary of one case is illustrative.

A Jewish chauffeur, aged 22, seen in 1920 complained of diabetes, which had begun in 1916. The early record has already been published.³ He passed into a more severe stage through several lapses from treatment, and though the insulin requirement was not extreme the lability of the blood sugar created unusual difficulties. Four insulin injections were given each twenty-four hours until a better plan was found in the timing method which I first described in 1924.⁴ During the following years the blood and urine were kept almost constantly normal on a diet of 80 Gm. of protein, 150 Gm. of

carbohydrate and 2,000 calories, divided into three meals and three extra periods of nourishment of 10 or 15 Gm. of carbohydrate (forenoon, afternoon and bedtime), with 68 units of insulin divided into doses of 30 units one hour before breakfast, 20 units immediately before lunch, and 18 units two hours after supper. Minor readjustments of both the quantities and the timing were made according to occasional tests, and the patient scrupulously followed the exacting program because of his experience of unpleasant consequences from even slight infractions. Some irregularities arose from the sensitiveness to exercise which is common in such cases. They were preventable whenever the patient could foresee the day's activities and add or subtract a few units of insulin. Otherwise he was subject to occasional heavy glycosuria on a day of rest and severe hypoglycemic attacks after especially heavy work. He was warned at the outset to change his occupation but ignored the advice because he knew of no other way to make a living. He thus has been the driver of a taxicab in New York City during most of the time since 1922 and has never had an accident. The saving feature has been that he invariably feels the beginning of one of his infrequent reactions in time to take a lump or two of sugar even in the midst of his driving. During this time he has married and has two children.

The trials of protamine insulinate were carried out during a period of unemployment. Preliminary studies of the blood sugar were made under direct observation and showed satisfactory delayed reduction with the protamine insulin. The later management had to be conducted at home, but the patient's intelligence and training qualified him for particularly accurate cooperation.

Two general plans were tried.

First a prolonged attempt was made to find any quantities or timing of doses that would control the sugar with one, two or three daily injections of the protamine insulin alone. This should theoretically be possible if the only new factor is a delayed absorption and if the convenience of injections by day or by night is ignored. This attempt was unsuccessful.

Second, combinations of old and new insulin doses were tried, given simultaneously or at different times according to the usual method of the Danish investigators. The finding of a satisfactory combined treatment seemed impossible, and the use of the protamine insulin had to be abandoned in this case.

Instead of a greater potency there was found an inability to control the sugar with considerably more than 68 units of the new insulin. On some occasions the dosage was raised as high as 96 units a day in the attempt to stop heavy glycosuria, which was terminated only with the onset of severe hypoglycemia. Instead of smoother blood sugar curves the fluctuations of hyperglycemia and hypoglycemia were more violent than with the old insulin. In one reaction at home the family had to give the semiconscious patient successive carbohydrate feedings up to a total of 100 Gm. before they could revive him. Instead of greater warning of reactions this patient, who had always had clear warnings became subject to attacks of mental confusion or deep unconsciousness, sometimes requiring large amounts of dextrose by vein. The unpredictable times of these attacks, which could not be prevented by any arrangement of injections and nourishment such as is feasible with the old insulin seemed to be only partly accounted for by a cumulative effect of the new insulin over several days. These irregularities of glycosuria and hypoglycemia were the essential cause of failure in this case.

Such difficulties seem to be tacitly implied in some of the earlier writings. The large experience of the Danish workers has apparently given them some reasons for preferring to retain at least one daily dose of the old insulin in most cases. Wilder and his associates describe the careful studies necessary for adjusting even the ordinary types of cases. The paper from Joslin's clinic mentions some difficulties and emphasizes that protamine insulinate is in an experimental stage also. Hagedorn is quoted as suggesting that the compound may not be absorbed at the same rate in all persons. Some of the troubles are presumably due to inexperience. Beyond this there may be some suspicion of irregular rates of liberation of insulin from the protamine compound in the same person, or other variations which may be inappreciable or unimportant in average patients but may have a magnified effect in the most severe or labile diabetic cases.

⁴ Arnold Lloyd. Personal communication to the author.

⁵ The possibility of the source of the dermatitis being an unidentified chemical in the "Kotex" could not be eliminated.

Whether due to lack of skill or to limitations of the method, such results are apt to lead to discouragement and undeserved condemnation if the new treatment is undertaken by the general medical profession with only the guidance of optimistic reports and without warning of difficulties or exceptions.⁵ The present experience suggests two conclusions

First, the present form of protamine insulinate is most fully adapted to the more moderate grades of diabetes. It has not settled the problem of the control of sugar in the most severe and difficult cases, in which the old insulin must still be used either partially or wholly

Second, the great fluctuations of blood sugar with the old insulin as revealed in some of the recent publications should mostly be prevented by proper timing and other simple devices. Likewise the best results with the new insulin will probably not be obtained on any arbitrary general plan but only by adaptation to meet individual needs

Since the foregoing was written, trials of the new metal compounds from Eli Lilly & Co., and of the Stearns crystalline insulin, together with developments in other laboratories, seem to indicate rapid progress toward the goal of dependable forms of insulin absorbable at different rates to suit the individual needs in different cases. Dr Hagedorn's brilliant work may therefore receive credit for the pioneer opening of what promises to be a new era of insulin treatment, apparently of greater complexity as well as greater success

Council on Foods

REPORTS OF THE COUNCIL

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENTS

FRANKLIN C. BING, Secretary

STATEMENT ON SCOPE OF CONSIDERATIONS OF THE COUNCIL ON FOODS

The Council on Foods has acted recently to limit somewhat the scope of products which it will include in the list of accepted foods. From its inception, the Council decided that fresh fruits and vegetables, fresh meats and eggs and ordinary milks embrace problems of food merchandising which are effectively controlled by local governmental agencies. The scope of products considered was accordingly confined to packaged foods or to foods treated by various means because of a desire to improve their nutritive qualities. The Council however, has always considered it to be a duty to review nutritional claims made in advertising of all food products when such action in the interests of the public and the profession is considered desirable

The Council now has decided to limit its scope further, believing that in so doing its facilities profitably can be concentrated on those food products which require its attention. Accordingly the Council has voted that the following products henceforth shall not be considered, as the need to pass on them no longer exists: ordinary breads and similar well known bakery products the nutritional features of which are generally recognized, frankfurters and other sausage products, carbonated beverages and their syrup bases, dyes for coloring foods and Easter eggs. If any products falling in the foregoing classes should be developed which have nutritional value beyond that of ordinary products, or if special claims are advanced, the Council will consider such claims and report on them when such action is considered desirable

Manufacturers and distributors of accepted products falling within the foregoing classes have been given a reasonable time to use up their present supplies of labels and advertising which bear the seal of acceptance.

⁵ Likewise Winnett, in an article of generally favorable tone (Winnett, E. B. The Treatment of Diabetes with Protamine Insulin. J. Iowa M. Soc. 28: 231 [May] 1936) concludes that much more clinical experience is necessary before protamine insulin is brought into general use.

The Council wishes to take this opportunity to express its appreciation to the manufacturers and distributors of the aforementioned products who have cooperated with the Council in its endeavors to encourage truthful advertising of wholesome food products

From time to time the Council may include other foods in the class of articles not falling within its scope

FOODS FOR WEIGHT REDUCTION

With the changes in the mode of living that characterize present-day urban existence, a considerable proportion of the adult population indulges in comparatively little muscular activity. Eating habits developed during adolescence when the demands of physical activity necessitate a large food intake, may be continued after the need for a high energy intake has ceased. The result is a gradual gain in weight, not conducive to the best health. It is hard for most people to believe how a small quantity of food can influence weight. An intake of 100 calories a day above the energy expenditure means an increase in weight of about 10 pounds in a year. Reducing by increased exercise is not an easy matter, frequently is ineffective, and in some cases may even be injurious. Those who wish to get rid of accumulated body fat must eat fewer calories than they expend in activity

Restriction of the energy intake must be accomplished without reduction of other dietary essentials. The daily intake of protein, minerals and vitamins should be much higher in proportion than that provided by the ordinary diet. Hence a reducing diet should be two or more times richer in these dietary essentials than the ordinary diet

It is now possible to plan for the person whose natural tendency is to eat beyond his caloric requirements a diet which will enable him to burn accumulated body fat and at the same time protect him from the dangers of undernutrition. This may be accomplished in a variety of ways, but the daily program must be definite and one that can be faithfully followed for a long enough period to achieve results. A reducing diet is most successful when it differs radically from the individual's eating habits. The natural foods of which such a diet principally ought to be composed are skimmed milk, leafy vegetables prepared without fat of any kind, fruits without added sugar, and lean meats. In addition, vitamins A and B₁ must be supplied in concentrated form

Under circumstances such that the foods named are obtainable with difficulty, special foods of low energy value may be used to enrich the reducing diet in protein, minerals and vitamins. These do not in the least do away with the necessity for restricting the energy intake, but they enable the person who cannot control the preparation of his own meals or does not know how to plan a diet of low caloric value rich in protein, minerals and vitamins to get a diet of higher nutritive value than would otherwise be possible. Taken in measured quantities, such special purpose foods also serve as a daily reminder of a different dietary regimen and a defense against the solicitations of family and friends to indulge in favorite foods

It is important that the contributions to the day's diet made by any so-called reducing food be clearly indicated. If the product is intended to replace one or two meals a day, suitable suggestions for the other meal or meals should be made. The advertising also should carry a statement that dieting to reduce is not without certain dangers, and it should be undertaken only under medical guidance.

Any foods which purport to reduce weight without alteration of the ordinary dietary program are either of little real value or contain drugs which ought not be administered without the supervision of a physician. Such foods will not be considered acceptable.

Foods intended as adjuncts to restricted diets will be accepted under the category of special purpose foods, with the restrictions as to advertising which apply to Special Purpose Foods, provided always that the name of the preparation is accompanied, wherever it appears on the label or advertising, by the statement "Food Supplement for a Reducing Diet"

SERUM TREATMENT OF ACUTE POLIOMYELITIS

In more than one locality this summer the perennial question of the efficacy of convalescent serum in acute poliomyelitis will again be raised. A diagnosis of poliomyelitis can be established in a large percentage of cases days prior to the onset of paralysis, particularly during an epidemic. In New York State¹ in 1931 the diagnosis was made in the preparalytic stage in 55 per cent of cases. The diagnosis and differentiation from other conditions is determined by examination of the spinal fluid in relation to the history and physical examination. It is assumed that early diagnosis offers optimal conditions for effective treatment with convalescent serum.

In a review of this subject in 1934, Harmon² could find no statistical proof of the value of any type of serum based on experiences recorded in the literature. He was careful to point out, however, the almost universal observation of rapid symptomatic response with a drop in temperature and improvement in symptoms, even with the small doses of serum that were in vogue at that time. He stated that this alone was enough encouragement to continue the use of convalescent serum. Park³ denied that convalescent serum had value, as a result of his summary of the observations of the pediatricians of the New York Academy of Medicine on the treatment of alternate cases during the New York City epidemic of 1931. Among 509 patients treated in the preparalytic stage the fatality rate was 38 per cent, as compared to a similar rate of 9 per cent in 408 untreated preparalytic patients. Among the treated group 68.8 per cent had no paralysis at any time, as compared to 73.7 per cent in the untreated group. Persistent paralysis after three to five months was noted in 19.6 per cent among the treated patients.

and in 11 per cent of the untreated. The strenuous epidemic circumstances under which these observations were made nullify to some extent the magnitude of the study and the value of the conclusions drawn. Indeed, in an almost simultaneous report of the same cases by the New York Academy of Medicine,⁴ it was said that "the untreated group was indeed a much milder group than the treated group. The results of the study are therefore inconclusive." In a smaller series of eighty-two cases in the same epidemic in Hartford, Conn., and in Brooklyn, Kramer and his co-workers⁵ were unable to find any far reaching difference between the treated and untreated cases, which were about equally divided in number.

In both of these studies, as well as in many contributions appearing before this time, the end result two or more years later is not known in relation to serum administration. It is now believed that orthopedic treatment is as much of an emergency procedure in acute poliomyelitis as the administration of serum and deserves equal attention by physicians who treat these patients. A fair estimate of probable recovery from paralysis cannot be made until the end of the first convalescent year. Indeed, many patients show some recovery of muscle strength during the second year. Until such end results are determined, serum should be administered in the early paralytic stage particularly in cases of slowly advancing paralysis and smoldering temperature elevation. The treatment of alternate cases with serum appears questionable from both the public health administration and the practical point of view.

Little attention has been given to the antiviral content of serums used for therapeutic purposes in man. It is well known that from 25 to 60 per cent of convalescents from poliomyelitis possess no neutralizing substances against the virus. This objection is obviated by some serum centers by preparation of pools of serum from fifteen to twenty donors. Even these serum pools do not neutralize the virus in dilutions beyond 1:10 to 1:50, varying with the technique used. Such facts point clearly to the need for concentration of serum or larger doses.

The few studies on treatment that have been made with pooled normal adult serum from man, which carries an equal or greater content of neutralizing substances, show that such serum gives practical results equal to those obtained with convalescent serum. The most potent neutralizing serums so far obtained have been produced in animals. These are not ready for application to man, since reactions from intraspinal administration contraindicate their use. Purification and limitation to extraspinal use might obviate the difficulties.

Data from the therapeutic tests of serum on experimental monkeys cannot be applied to the human disease.

4 Report of Study of Administration of Convalescent Serum in Treatment of Poliomyelitis. Bull. New York Acad. Med. 8: 613 1932.

5 Kramer S D, Aycock W L, Solomon C I and Thomsen C L. Convalescent Serum Therapy in Preparalytic Poliomyelitis. England J. Med. 206: 432 (March 3) 1932.

because of the difference in severity of the disease and the difficulty in management of monkeys with the acute disease. Thus the observations of Brodie,⁶ Gordon⁷ and Schultz and Gebhardt⁸ that convalescent or other neutralizing serum had no effect on the experimental disease, even if administered early, cannot be directly applied to man. However, it must be remembered that some prophylactic value was observed for serum by Schultz and Gebhardt⁹ in experimental monkeys, as they reduced the mortality of that fulminating disease from 7 per cent surviving to 30 per cent. Even though it is improbable¹⁰ that any type of antibody can reach the virus once virus cell union has taken place, neutralization of virus in dead cells and that in transit from cell to cell can take place. So little is known about the distribution of virus in the cord during the preparalytic stage in man that spread within the cord may take place during this and later stages, so that there may be some effect of antibody even at these stages. There are no experimental data on the penetration of antibody into the nervous system at any stage of the disease.

While it is contended by some that there is a smaller incidence of paralysis in the group of cases diagnosed in the preparalytic stage than in those seen after paralysis has set in, independent of serum administration, such a conclusion is not certain, as cases seen after paralysis frequently give a history of a prolonged preparalytic phase. However that may be, the practical results that have been obtained in three recent reports are alone enough evidence to warrant continued use of serum. Jensen¹¹ in the Denmark epidemic of 1934 found there was less acute paralysis, the earlier serum was given in the preparalytic stage, but reported a low total incidence of paralysis. Cowie and his co-workers¹² have reported no residual paralysis in eighty preparalytic cases treated with both human convalescent serum and transfusions from normal adults. Levinson,¹³ in 149 preparalytic cases of the seasonal endemic type in the Chicago area during the past four years observed paralysis in only a few cases. This for the most part, disappeared within a few weeks. He has been especially impressed by the decline of acute symptoms in both the preparalytic group and in early paralytic cases following serum administration.

Large doses of convalescent serum (100 cc or more) given intravenously and small doses (from 10 to 15 cc)

intraspinaly at the time of the spinal puncture are recommended. The intravenous dosage should be repeated in from twelve to twenty-four hours if the temperature is still elevated or symptoms are not subsiding. If future epidemic results can duplicate those here mentioned, the treatment of acute poliomyelitis will be satisfactory and harmless to the patient. There is no other treatment that is even of debatable value. The early and continued use of orthopedic measures will improve results in the acute paralytic disease and in cases in which only paresis appears.

MAD DOGS AND MR. TERHUNE

The recent cinema on the life of Pasteur reacquainted hundreds and familiarized thousands with the importance of the Frenchman's contributions to science. The lay world knows him best as the conqueror of rabies, that common knowledge has played a real part in the acceptance by laymen of the prophylactic treatment of the dread disease. As a result there has been cooperation with the medical profession in waging effective war against it, and the incidence of this animal-borne infection has been greatly reduced in practically every corner of the world. When attention lapses, however, rabies promptly assumes menacing proportions, as illustrated by the quarantine on dogs recently instituted in Cook County, Ill., because of the high incidence of rabies found in dogs that have bitten Chicagoans.

Unfortunately, a lowered incidence of smallpox, rabies or diphtheria always seems to bring scoffing by antivaccinationists, antivivisectionists and others, who charge that attempts to continue prevention constitute a racket. An example of this subversive attitude is an article by Albert Payson Terhune,¹ author and dog fancier, in the August 1936 *Reader's Digest*. The article is well titled—"Beware of the Dog"—and consists for the most part of advice on how to avoid being bitten by a dog. Mr. Terhune, as a well known lover of dogs, is qualified to give this advice and most of it seems entirely reasonable. Unfortunately he includes this additional "information":

One or two more advisory tips. If your technique fails and you are bitten by a dog remember this—not once in many thousand times is the dog rabid. Rabies exists, but it is very rare. Of the almost uncountable bites inflicted during a term of years on attendants in the New York City dog pounds, not one caused a case of rabies.

The bite of a healthy dog is only as dangerous as would be a similar wound inflicted by a piece of metal or bone—plus such possible food infection (not rabies) as may have been on the animal's teeth. If the bite is where your lips can reach it suck it out thoroughly. Then bathe it in luke warm (not hot) water and paint it with iodine. And don't worry. You are in no danger.

If you are afraid the biter had rabies—which he almost never has—use the same treatment but paint the wound with carbolic acid instead of iodine. The acid will burn for a short time but you will be safe.

This advice certainly leaves the reader with the impression that rabies is something that probably won't

happen anyhow, and that at any rate this treatment is entirely adequate. Granted that the incidence of rabies was decreasing in most countries before 1914, that following the World War there was an increase in the number of rabid animals and in human rabies, and that since 1924 "*with the restoration of control measures*"² [italics ours], it is not granted that the disease is so rare as to warrant Mr. Terhune's lackadaisical attitude.

The following statistics are interesting in connection with Mr. Terhune's figures from the New York City dog pounds. They appeared in an article by Lois Stice³ in the July 1935 *Hygeia*.

The health department of Ohio, for instance, recently reported that from Jan. 1, 1934, to March 15 this year [1935], the state laboratory found that 416 out of 1,922 dogs' heads sent to the laboratory for examination showed infection with rabies. During the past ten years fifty-eight persons have died of rabies in Ohio, and other states can probably produce similar records. In these cases health officers usually find that Pasteur treatment was not given or that it was begun too late to win the race with the deadly infection.

An article by Cornwall⁴ in the *British Medical Journal* in 1923 included these figures:

| | |
|--|-------------|
| Number of persons bitten (by animals proved to be rabid) and not given Pasteur treatment | 423 |
| Dead from hydrophobia | 148 |
| Mortality | 35 per cent |

The first Pasteur treatment was given almost fifty years ago and yet the figures from Ohio are for the last year and the last decade and Cornwall's series was reported only thirteen years ago. The failure of victims to avail themselves of this formidable weapon against a disease that is always fatal² can be attributed largely to ignorance, carelessness, indifference, and the widespread dissemination of such advice as that found in Mr. Terhune's article.

The least that can be done in case of dog bite is to cauterize the wound and place the biter under observation in the city pound or a dog hospital. If he develops the disease, begin the Pasteur treatment at once if it has not already been started. If the dog is alive and well at the end of the three weeks, he did not have rabies when he inflicted the wound.⁵ The inconvenience to the dog cannot be weighed in the balance with a horrible death of a human being from rabies. Anyone who has ever seen a child die of this disease would have no hesitancy in making a decision. Although time is an all important factor in the cauterization of these wounds, Mr. Terhune's self cauterization should be recommended only if a physician is not available. His comparison of dog bites with other more ordinary wounds is not warranted because of the many pathogenic organisms found in the dog's mouth.

The effectiveness of the Pasteur treatment cannot be denied or even questioned. True, in adults⁴ there is an occasional case of paralysis following vaccination (3 in 20,000)⁶ which is generally transient (but some times fatal), but this is certainly no contraindication to its use. In ninety-nine out of every hundred cases treated, Pasteur treatment protects against a disease that is always fatal once it develops.² A mortality of 1 per cent in those bitten by rabid animals compared with Cornwall's⁴ figure of 35 per cent should leave no doubt in the mind of any one that it is a most useful measure.

When the average man wants a dog he should consult a dog fancier. But when a dog bites a man the breeding and training of the dog are not matters of chief concern. The possibility of rabies and its prevention are matters for public health officials and physicians. The *Reader's Digest* served its readers badly when it promulgated Mr. Terhune's advice on dog bites.

THE HEALTH OF WOMEN

The profound economic and social changes that have occurred in the lives of most American women and those of other civilized countries during the last fifty years have directed new interest to the health problems which concern women particularly. Theobald¹ has recently considered some effects of "emancipation" on the health of women. The freedom that has resulted from the achievement of economic independence of women has played and continues to play, he believes, a distinct rôle in the causation of maternal mortality. The deleterious effect is based on the fact that it is frequent for women to continue in unsuitable occupations late into pregnancy and also that independence has probably resulted in a marked increase in the number of abortions. While there are probably many advantages in the relatively free association of the sexes, Theobald believes that many undesirable features have accompanied the changed situation. He believes that some effort should be made to educate the young concerning their personal responsibilities resulting from the "new freedom." Furthermore, the economic conditions that have led to the "taxi" dance halls and their equivalents should be remedied if for no other reason than the effect on maternal mortality.

Competitive sports among women have increased to a degree unprecedented in recent times. Theobald believes that physical exercise is as good for women as it is for men but that excessive exercise is more harmful to women than to men. Biologically it must be axiomatic that nothing can be good for a girl that renders her less capable of maternity. Exercise by itself does not appear to have a harmful effect on child bearing, but it is not yet determined whether violent exercise exerts any effect on the development of the

¹ Theobald, Geoffrey. *Some Effects of Emancipation on the Health of Women*. *J. State Med.* 44: 359 (June) 1936.

uterus or on subsequent fertility. The modern cult which permits even violent exercise during menstruation has no sound foundation. The nervous strain of competitive sport is probably greater for women than for men. The indulgence in competitive sports, from the author's observations, seems to have little effect on the posture of women, which in itself is probably of considerable importance. Few of the picked British female athletes had really good chest expansion and many were anemic. The mental aspects of women's emancipation may be equally important. As one critic of the modern girl said, "She demands to be treated as an equal, she expects to be treated as a duchess and she behaves like a washerwoman." Theobald goes on to say

She copies the coolie woman of the Chinese bazaar in plucking her eyebrows, the Siamese peasant in bobbing her hair, the Arab in letting her nails grow like claws and painting them a hideous red, the courtesan in painting all visible parts of her anatomy, and in painting and powdering herself in public betrays incredible vulgarity. She is so restless that she cannot sit peacefully at home, she cannot eat her meals without smoking, and is unhappy unless she is at the dance or cinema.

Although probably more applicable to the particular than to the general, no exception can be taken to the thesis that wanton expenditure of nervous energy begets nervous instability. But it is still too soon to determine what the ultimate effects of mass removal of women from the home will have on their nervous systems and those of their descendants. The question is debatable and if the divergences from biologic normality are not too great the results can be good as well as evil.

Perhaps a corollary of the so-called emancipation of women is the specific health problem that is faced by women who marry. Goodwin² states that when a woman marries there are four main directions in which her life is to be altered profoundly: (1) responsibility for domestic management, (2) companionate life, (3) sex life and (4) reproductive life. With possible occasional exceptions these are all to be new experiences which may in one form or another profoundly affect a woman's physical and mental health. The responsibility for domestic management generally involves a much greater output of physical energy than that to which a woman has been accustomed. This fact should be realized by both parties and attempts made to minimize the possible danger of sudden change by various expedients, such as the adoption of a definite period of rest each day. The problem of companionate existence for a woman who marries is likely to be more difficult than for a man. This is largely because most men have been always to some extent dependent on female supervision while a woman generally develops a philosophy of independence to the opposite sex. Furthermore, a woman cannot so easily escape the problems which the changed mode of life occasion. The third great change, that dealing with sexual life, has lately received much

more adequate medical recognition, but it is certainly still true that in civilized Anglo-Saxon communities the adaptation is usually more abrupt and more difficult than it should be. Preliminary education should do much toward solving this problem. Finally, the problem of reproduction is one which practically every married woman has to face at some time. Here again the possibilities for physical and mental damage to the health are numerous. If carefully contemplated, both physical and mental reactions, however, can be modified in the proper direction. In spite of these difficulties, which might lead one to believe that the health of a married woman is more precarious than that of her unmarried sister, the reverse is actually the case. The biologic norm is more closely fulfilled by marriage, and there can be no question that marriage will increase rather than diminish the mental and bodily well being of a woman, provided simple rules of health are followed.

The questions brought out in these two articles are provocative. The significance of such studies is important from the point of view of individual health and also from that of the community.

THE MARCUS WHITMAN CENTENNIAL AT WALLA WALLA

The American Medical Association and other national organizations will participate in a four day celebration at Walla Walla, Wash., August 13-16, to commemorate the career of the first American physician to practice west of the Rocky Mountains and the first white man to establish a home in the Northwest country—Dr. Marcus Whitman. On a widely varied program Dr. Frederick C. Waite of Western Reserve University, Cleveland, will speak Thursday morning in Pioneer Park on "The Medical Education of Dr. Marcus Whitman." "Medical Practice One Hundred Years Ago" will be the subject of an address by Dr. Olof Larsell of the University of Oregon. The subject of an address by Dr. Harold Behneman of Stanford University will be "One Hundred Years of American Medicine." A portrait of Dr. Whitman, presented by the physicians of the Pacific Northwest, will be unveiled and the public will be invited to the museum of Whitman College, where the medical instruments and books used a hundred years ago will be on exhibition. The second day's celebration will be in honor of Mrs. Whitman, who accompanied her illustrious husband into the Northwest and became the mother of the first American white child to be born west of the Rocky Mountains. The third day will be historians' day, and Sunday will be a religious day. Born in New York in 1802, Dr. Whitman attended the College of Physicians and Surgeons at Fairfield and some years later established himself in practice at Wheeler, N. Y. Dr. Whitman's ambition was to become a medical missionary in the great unexplored Northwest. Although rejected by the American Board of Missions on account of ill health, he persisted and finally received an appointment to

² Goodwin, Aubrey. The Health of the Married Woman. J. State Med. 44: 249 (May) 1936.

accompany Samuel Parker on his explorations Dr Whitman was to be taken aboard the boat of the American Fur Company at Liberty Landing, Mo., but after he had waited three weeks for the boat to arrive it passed him by at the wharf. The Whitman party then proceeded overland through rough and dangerous Indian territory, reaching Fort Walla Walla on the Columbia River Sept 1, 1836. Dr Whitman set about to establish a chain of missions among the various Indian tribes and to explore this country on behalf of the United States. He drove in covered wagons many hundreds of miles over roadless and mountainous land to Fort Boise, to Fort Hall, and back and forth to the missionary stations which he had established and rode thousands of miles over trails no other white man had ridden before, to care for the sick. Other settlers began to trickle into this great undeveloped country and they brought with them some of the contagious diseases. Epidemics of measles and scarlet fever broke out among hostile Indian tribes among whom Dr Whitman had practiced his profession, and many Indians lost their lives. It was a custom in some tribes to slay the medicine men who failed to save the lives of the sick, and that custom is believed to have led to the massacre in which Dr and Mrs Whitman were slain, together with several others on the mission grounds. More than fifty women and children were held as captives by the Indians until ransomed by the fur company. At Wanlatpu on the site of the Whitman mission and home stands the Whitman monument, erected on the fiftieth anniversary of the massacre in 1897. Congress has made this mission site a national monument. Thus through these memorials Dr Whitman's life will continue to inspire others to devote themselves to their country and to the traditions of the medical profession.

CALIFORNIA

Society News—At a meeting of the San Joaquin County Medical Society in Stockton June 4 Dr Charles A. Broadus, Stockton, among others, discussed "Balance of Eye Muscles."—Dr Joseph L. McCool, San Francisco, addressed the Humboldt County Medical Society, June 3, on "Strabismus—Etiology and Treatment."—Funds have been appropriated to establish a department of public health nursing at the University of California at Los Angeles with full academic status.

Graduate Courses—Stanford University School of Medicine cooperating with the San Francisco Department of Health and the San Francisco Hospital will offer graduate courses in the specialties for practicing physicians, September 14-18. There will be a registration fee of \$25, entitling each physician to take a morning and afternoon course and attend all the general meetings. All applications must be mailed to the dean Stanford University School of Medicine, 2398 Sacramento Street San Francisco, not later than September 10. The subjects covered will include obstetrics and gynecology, gastroenterology, pediatrics, cardiology, hypertension and nephritis, neurology and psychiatry, fractures and traumatic surgery and proctology. The general meetings will deal with x-ray therapy, backache, blood diseases and the diagnostic methods and therapeutic agents of syphilis.

GEORGIA

Outbreak of Malaria—Newspapers reported an outbreak of malaria in Cobb County, July 10, which approached an epidemic. There were about 100 cases, most of which were said to be in the southern part of the county. Plans are being hastened to dredge creeks and low lying areas in the country it was stated.

ILLINOIS

First Outbreak of "Milk Sickness" This Year—The state department of health reports that an outbreak of 'milk sickness,' the first recorded this year, "occurred in Perry County in June, affecting five members of one family living on a farm near Denver. The source of the illness, apparently, was milk from cows that had eaten white snakeroot, a poisonous plant that grows in moist, shady places. The disease is now rare, although it was formerly common in Illinois. Settlers are said to have avoided large areas in Illinois for fear of milk sickness during pioneer days, when the disease was known as "Indian trembles." In *THE JOURNAL*, Dec 8, 1928, an item based on an article in the *Atlantic Monthly* by Wilma Frances Minor stated that when the Lincoln family migrated from Kentucky to southern Indiana, their first shelter in Indiana was a shack on a half acre which Thomas Lincoln cleared on Little Pigeon Creek, not far from the Ohio River. When they moved into a more substantial cabin later, about them grew a poisonous plant known as snake-root, deerwort or squaw-weed. "Cows eating it developed a strange malady which attacked also the people who drank their milk. With this mysterious disease Nancy [Abraham Lincoln's mother] became infected. Betsy and Thomas Sparrow, Nancy's aunt and uncle, who, with her cousin Dennis Hanks, had come to live with the Lincolns, had already been stricken and died. Now, in October, 1818, Nancy herself succumbed. In 1830, occurred another epidemic of 'milk sick.' Mrs Lincoln was alarmed [Abraham's father had remarried] and again the family moved, Thomas Lincoln disposing of his land to James Gentry, and journeying with his wife and Abraham 200 miles to a thickly wooded spot on the bluffs of the Sangamon River about six miles west of Decatur, in Macon County, Illinois."

Chicago

Personal—Dr William Allen Pusey was recently elected an honorary member of the Austrian Dermatologic Society.—Dr Percival Bailey, professor of surgery and neurology, School of Medicine, Division of Biological Sciences, University of Chicago, gave a lecture in Carmi, July 2, on the history of the Armenian village Zeitouri in Asia Minor.

Society Sponsors Window Exhibits—A lobby window in the Annex Building of Marshall Field and Company has been given to the Chicago Medical Society, free of rental and service charges, for the display of health educational material. The exhibit now on display is a moving, electrically lighted model showing the circulatory system, lent by the University of Illinois College of Medicine. The background of the window is an allegorical painting representing figures of heart disease, pneumonia, cancer, nephritis and tuberculosis. There is also a card in the window giving the number of deaths from these diseases in Illinois during the first four months of 1934 as reported by the state department of health. The first exhibit, presented early in July, was on eye injuries, especially those caused by Fourth of July accidents. The displays are planned and prepared by the educational committee of the Illinois State Medical Society.

KANSAS

Personal—Dr Francis A. Carmichael has resigned as superintendent of the state hospital for the insane in Osawa-tomic, effective August 1, after twenty-three years service.—Announcement is made of the appointment of the following physicians to the Kansas State Board of Health: George I. Thacher, Waterville; Harry L. Aldrich, Caney; Walter J. Eilerts, Wichita and William C. Lathrop, Norton.

Society News—At a joint meeting of the Brown County Medical Society and the Brown County Dental Study Club in Hiawatha, June 26 Dr Walter Roger Moore, St. Joseph, Mo., among others discussed "Immunization Against Contagious Diseases."—Dr Edward H. Skinner, Kansas City, Mo., was the guest speaker at a meeting of the Butler-Greenwood County Professional Society in Eureka, June 19. He spoke on "Practical Methods for Control of Cancer."—Dr Emmannuel Raymond Gelvin, Concordia, addressed the Clay County Medical Society in Clay Center, June 8 on "Management of Acute

Empyema."—Among others, Dr Edgar A Hines Jr, Rochester, Minn, addressed the Ford County Medical Society in Dodge City, June 12, on "Essential Hypertension."—Among others, Dr Kellogg F Bascom, Manhattan, addressed the Golden Belt Medical Society in Manhattan, July 2, on "Some Aspects of the Anatomy and Physiology of the Testis."—Speakers before a recent meeting of the Reno County Medical Society in Hutchinson included Dr John A Dillon, Larned, on "The Psychiatric Point of View."—The medical societies of Marion, Harvey and McPherson counties held a joint meeting in Newton, June 1, speakers were Drs LaVerne B Spake, Kansas City, on "Acute Infections of the Ear and Mastoid", John A Billingsley, Kansas City, "Acute Inflammations of the Eye," and Fred E. Angle, Kansas City, "Undulant Fever and Its Treatment."

MASSACHUSETTS

Alumni Reunion—Dr David L Belding Hingham, was chosen president of the Alumni Association of Boston University School of Medicine at its recent reunion, and Dr Rudolph Jacoby, Newton, was named secretary. Speakers included Dr Winfred Overholser, commissioner of the state department of mental diseases, Daniel L Marsh, Ph.D., president of Boston University, Dr Alexander S Begg, dean of the medical school, Dr Reginald Fitz, Wade professor of medicine, Dr Henry Clute, professor of surgery, and Mr Walter Mulvihill, Worcester, president of the senior class. Dr Cecil W Clark was toastmaster.

Outbreak of Typhoid—The New York Times reported an outbreak of typhoid in Lowell involving forty-three cases and one death between June 21 and July 25. Sixteen were children in St Joseph's Orphanage. The origin of the outbreak is believed to have been the St John's Day banquet sponsored by the Union St. Jean Baptiste, June 21, in Lowell. The Times reported that the outbreak had been traced to a carrier who was a milk handler. Health authorities in New Hampshire and Rhode Island were urged to watch for typhoid, since several persons from these states attended the dinner. The first immunization clinic was opened in Lowell July 21, and up to 1 p.m. 286 persons had taken advantage of this service. In addition, more than 200 persons who attended the dinner both as guests and as food handlers were immunized.

MISSISSIPPI

Society News—At a meeting of the Mississippi State Pediatric Society in Jackson, July 2, Dr Harvey F Garrison, Jackson, was elected president, Dr John K. Bullock, Jackson, vice president, and Dr Guy C Jarratt, Vicksburg, was reelected secretary.—The North Mississippi Medical Society was addressed in Como, July 15, by Drs Dudley R Moore, Byhalia, on coronary thrombosis, John C Culley Oxford, treatment of fractures, and William W Walker, Memphis, complications of pregnancy.

Health Department News—The state department of health announces that after August 1 no certificates for births occurring more than two years ago can be accepted. A recent WPA project has dealt with checking these records in an effort to obtain missing information. Birth records were searched from November 1912 through the year 1927.—The Commonwealth Fund is considering the selection of a third county in Mississippi for its cooperative service. Either Jones or Lowndes County will be chosen, it is reported. The fund is now assisting the units in Pike and Lauderdale counties.—Dr Ransom J. Jones has been named director of the Pearl River County Health Department, with headquarters in Poplarville. He succeeds Dr Cecil C. Smith, who has been named full time health officer for the newly organized unit in Madison County, with headquarters at Canton.

NEBRASKA

Health at Omaha—Telegraphic reports to the U.S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended July 25 indicate that the highest mortality rate (25.8) appears for Omaha and the rate for the group of cities as a whole was 11. The mortality rate for Omaha for the corresponding week of last year was 13 and that for the group of cities, 10.2. The annual rate for the eighty-six cities for the thirty weeks of 1936 was 12.9 as compared with 11.9 for the corresponding period of 1935. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that a city is a hospital center for a large area or that it has a large Negro population may tend to increase the death rate.

NEW MEXICO

Study of Dysentery—The National Institute of Health, U.S. Public Health Service, is continuing a study begun in 1935 of the cause of summer diarrhea in New Mexico. Dr Albert V Hardy, New York, is director of the study and the staff includes Martin Frobisher, Sc.D., Baltimore, Bertha Kaplan Spector, Ph.D., Chicago, Dr James Watt, U.S. Public Health Service, and Dr Teresa McGovern, New York.

Health Officers' Conference—A conference of district health officers was held in Santa Fe, July 9-11, with the state bureau of public health. Among other speakers, Dr John Rosslyn Earp, Santa Fe, state health officer, discussed public health administration, Dr George S. Littell, Santa Fe, director of child health, the maternal and child health program and Dr Albert V Hardy, New York, dysentery. A resolution was adopted urging the New Mexico Pharmaceutical Association to take whatever steps it finds practicable to discourage and to prevent the prescription by drug store clerks and pharmacists of remedies for syphilis and impress on their customers the importance of immediate medical treatment.

NEW YORK

Milkborne Epidemic of Septic Sore Throat—Forty-two cases of septic sore throat in a village of 666 inhabitants were reported in *Health News*, June 22. A culture from a milk handler on the dairy farm was found positive for the hemolytic streptococcus. He had been ill with septic sore throat May 30. Pasteurization of the suspected milk supply was put into effect June 11.

Society News—The Central New York Pediatric Club held a meeting in Rochester recently, with the following speakers, among others: Drs Samuel W. Clausen, on "Alleged Harmful Effects of Cod Liver Oil", Paul W. Beaven, "Incidence of Tuberculosis in Children", Jerome T. Syverton, "Recent Advances in the Study of Influenza", and Charles M. Carpenter, "Undulant Fever in Children".—The Western New York and Ontario Urological Society, branch of the American Urological Association, will hold its next meeting at the Guthrie Clinic, Sayre, Pa., October 10.

Dr Dougherty Made Secretary Emeritus—At the recent annual session of the Medical Society of the State of New York, Dr Daniel S. Dougherty, New York, secretary of the society since 1925, was made secretary emeritus. The emeritus position was created by the house of delegates to continue during Dr Dougherty's lifetime. Dr Dougherty has been secretary of the Medical Society of the County of New York since 1916. He is 75 years old and was graduated from New York University College of Medicine in 1884. For many years he has been professor of otology at New York Polyclinic Medical School and Hospital.

New York City

Death from Rabies—A 2 year old child died of rabies July 25 in Queens General Hospital, after having been bitten by a dog June 27, the New York Times reported. It was said that this was the first death from the disease ever listed in the borough. The biting of several others by dogs has recently been reported and police issued warnings against unmuzzled dogs.

WPA Workers Assigned to Marijuana Eradication—Squads of WPA workers specially trained to recognize marijuana have been placed on duty in the boroughs of the Bronx, Brooklyn, Queens and Richmond to eradicate the weed from vacant lots, in cooperation with the police and health departments. Each squad is accompanied by an officer from the narcotics squad of the police department, who is responsible for turning the weed over to the police for destruction. So far this year the Brooklyn squad has dug up seventeen tons in all four boroughs about forty tons have been eradicated. To prevent spread of the weed it is necessary to dig up the root completely since it sometimes multiplies ten times from one season to the next.

Changes in Staff of Rockefeller Institute—The Board of Scientific Directors of Rockefeller Institute for Medical Research announce the promotion of Dr Irvine H. Page from associate to associate member, Alexandre Rothen, Sc.D., Dr John M. Steele and Robert S. Tipson, Ph.D., from assistant to associate. Dr William Halsey Barker, Rollin D. Hotchkiss, Ph.D., Hubert S. Loring, Ph.D. and George L. McNew, Ph.D., from fellow to assistant. The following new appointments were also announced: Dr Rafael Lorente de No, formerly of

Washington University School of Medicine, St. Louis, associate, Dr Robert D Baird, New Haven, Conn., Dr George K. Hirst, Cleveland, Dr Horace L Hodes, Baltimore, Dr Austin L Joyner, Durham N C, Charles L Mehlretter, Ph.D., Bridgeport, Conn., Dr Benjamin F Miller, New York, Carl G Nieman, Ph.D., Madison Wis., Dr John A. Saxton Jr., St. Louis, and Leonard C Kreider, Ph.D. assistants, Dr Carl G Hartford, St. Louis, and August A Di Somma, A.B., New York, fellows. These changes were effective July 1.

PENNSYLVANIA

Society News—Dr Oliver E. Mattas, Altoona, addressed the Blair County Medical Society, Altoona, recently on "Treatment of Acute Gonorrhea in the Male."—Dr Frank A. Evans, Pittsburgh, addressed the Crawford County Medical Society, Meadville, recently on "Essential Foodstuffs."—Dr Samuel D. Shull, Chambersburg, presented a paper on leukemia at a meeting of the Franklin County Medical Society in Chambersburg recently.—Dr Leonard G. Rowntree, Philadelphia, addressed the Luzerne County Medical Society, Wilkes-Barre, recently on "Organotherapy from the Internist's Point of View."—Dr Samuel Wolman, Baltimore, addressed the Cambria County Medical Society, Cresson, July 9, on tuberculosis.

SOUTH DAKOTA

Society News—Dr Anders E. Johnson, Watertown, was recently elected president of the South Dakota Academy of Ophthalmology and Otolaryngology and Dr F. C. Nilsson, Sioux Falls, vice president. Dr Howard L. Saylor, Huron, was reelected secretary.

Tuberculin Tests in Cattle Not Mandatory—The supreme court of South Dakota handed down a ruling June 24 that mandatory testing of cattle cannot be carried on under existing laws. The decision will prevent the state department of agriculture from forcing farmers to submit their cattle to tuberculin tests.

TEXAS

Testimonial to Physicians—Drs John T. Moore and Marvin L. Graves, Houston, were guests of honor at a dinner given by Harris County physicians June 17 at the Houston Club. The two physicians were recently made members emeritus of the Texas State Medical Association. Dr Claude C. Cody was toastmaster, and congratulatory speeches were made by Drs Howard R. Dudgeon, Waco, president of the state association, Birt T. Vanzant, Charles C. Green, J. Edward Hodges, Moise D. Levy and Merle B. Stokes, Houston. Engraved signet rings were presented to both guests of honor. Both are former presidents of the state medical association.

WASHINGTON

The Marcus Whitman Centennial—As noted in the editorial pages in this issue, the one hundredth anniversary of the arrival in the Pacific Northwest of Dr Marcus Whitman will be celebrated at Pioneer Park in Walla Walla, August 13-16. The first day of the observance will be devoted to honoring the memory of Dr Whitman. Dr Park Weed Willis, Seattle, representing the American Medical Association, will preside and addresses will be made by Frederick C. Wate, Ph.D., Cleveland, on "The Medical Education of Dr Whitman", Olaf Larsell, Ph.D., Portland, Ore., "The Practice of Medicine One Hundred Years Ago" and Dr Harold M. F. Behneman, San Francisco, "One Hundred Years of Medical Progress." In the afternoon a portrait of Dr Whitman will be presented to Whitman College by physicians of the Northwest in a ceremony at which speakers will be Drs James L. S. Stewart, Boise, Idaho, representing the contributing physicians, Dr Ralph A. Fenton, Portland, representing the American Medical Association, and Mr Allen H. Reynolds, president of the board of trustees of Whitman College. The second day of the centennial is dedicated to Dr Whitman's wife as a pioneer mother, musician and teacher. Saturday August 15 will be "Historians' Day" and Sunday a commemoration of Dr Whitman as a missionary. Each day there will be a parade picturing the development of the Northwest emphasizing the program feature of the day. Each evening an outdoor pageant built around the lives of Dr and Mrs Whitman will be presented. Dr Whitman is believed to have performed the first surgical operation west of the Rocky Mountains when he removed an arrow head from the head of Jim Bridger the famous Indian scout.

WISCONSIN

Cancer Institute at State University—The University of Wisconsin Medical School, Madison, announces a cancer institute to be given under the auspices of the Alumni Research Foundation, September 7-9. The first day's addresses will be on "Cancer and Inheritance," the speakers being Dr Lew Kreyberg, Oslo, Norway, Dr Madge Thurlow Macklin, London, Ont., Clarence C. Little, Sc.D., Bar Harbor, Maine, Edgar Allen, Ph.D., New Haven, Conn., and Howard B. Andervont, Sc.D., biologist, U. S. Public Health Service, Boston. Dr James Ewing, New York, will speak Monday evening on "Cancer, a Public Health Problem." Speakers Tuesday will be Gioacchino Failla, Ph.D., New York, on "Influence of Wavelength on the Biologic Action of Radiation", Dr Henri Coutard, Radium Institute, University of Paris, "Reaction of Tissue Cells to Irradiation", Dr Warren H. Lewis, Baltimore, "Tissue Study in the Study of Cancer", Dr Stanley P. Reimann, Philadelphia, "Biology of the Cancer Cell", and Dr James B. Murphy, New York, "Filtrable Viruses in Malignant Neoplasms." Wednesday's session will be a joint meeting with the State Medical Society of Wisconsin, at which the following addresses will be presented:

Dr Ewing, Biopsy in the Recognition and Treatment of Early Malignancy.
Dr Murphy, Relation of Filtrable Viruses to Malignant Neoplasms.
Dr Andervont, Effect of Bacterial Products on the Growth of Malignant Tumors.
Dr Emil Novak, Baltimore, Recognition and Treatment of Early Malignant Lesions of the Uterine Cervix.
Dr Coutard, Treatment of Cancer of the Breast.
Dr Kreyberg, Genetic and Constitutional Aspects of Spontaneous and Induced Tumors.
Dr Allen, Glandular Dysfunction and the Development of Malignant Tumors.
Dr Macklin, Occurrence of Cancer in Different Individuals of the Same Family.

There will also be round tables Monday and Tuesday afternoons on diagnostic problems, filtrable viruses, surgery and irradiation, cytology and etiology. Dr Little will address a public meeting Tuesday evening in Great Hall, Memorial Union, on "A Program for the Control and Prevention of Cancer." Glenn Frank, LL.D., president of the university, will give an address at the opening session.

GENERAL

New Offices of Ophthalmology Board—The American Board of Ophthalmology announces the removal of its executive offices to Room 1002, Beaumont Medical Building, 3720 Washington Boulevard, St. Louis, July 1. Dr John Green is secretary-treasurer.

Academy of Tuberculosis Formed—The American Academy of Tuberculosis Physicians was organized at a meeting in Kansas City, Mo., recently. Membership is open to physicians specializing in tuberculosis and other diseases of the lungs. Officers are Drs Charles O. Giese, Colorado Springs, president, J. Arthur Myers, Minneapolis, and Samuel H. Smider, Kansas City, vice presidents, and Arnold Minam, Denver, secretary-treasurer. Dr William T. Little, Paducah, Ky., was chosen historian.

Society News—The American Nurses' Association, the National League of Nursing Education and National Organization for Public Health Nursing held their biennial convention in Los Angeles, June 21-26.—The National Conference of Catholic Charities was held in Seattle, August 2-6. Speakers included Rev. Alphonse M. Schwitalla, S.J., dean, St. Louis University School of Medicine, St. Louis, president of the Catholic Hospital Association of the United States and Canada on "Medical Social Service and Outpatient Departments" at a meeting of the committee on health (physical division).—National Pharmacy Week will be observed for the twelfth year during the week of October 19.

Prevalence of Infantile Paralysis—Five hundred and twelve cases of infantile paralysis had been reported in thirty-eight states since June 13, according to an announcement from the U. S. Public Health Service appearing in the New York Times, July 31. Alabama led the list with 209 cases and Tennessee was second with sixty. California had fifty-two, Illinois twenty-seven, New York twenty-four and Mississippi fifteen. Several states had only one case, it was stated. For the week ended July 30, 117 new cases were reported, two fewer than during the preceding week. Alabama reported thirty-nine new cases, compared to thirty-five the previous week. States in which the disease had not been reported were New Hampshire, Wisconsin, Minnesota, South Dakota, Nebraska, Delaware, Arkansas, Wyoming, Colorado, Oklahoma and the District of Columbia.

The Sesquicentennial of the Constitution.—The United States Constitution Sesquicentennial Commission, established by a resolution of Congress in 1935, has announced tentative plans for celebration of the one hundred and fiftieth anniversary of the formation of the Constitution. The celebration will begin Sept. 17, 1937, and continue through April 30, 1939, the sesquicentennial of the inauguration of Washington as President, the day on which the World Exposition in New York will be opened. The President of the United States is chairman of the commission and its membership includes the Vice President, the Speaker of the House, five Senators, five Representatives and five commissioners appointed by the President. It is planned to have the initial celebration in Philadelphia at Independence Hall, where the Constitution was signed, special celebrations in the original thirteen states on the anniversaries of the dates on which their respective conventions ratified the Constitution, and celebrations in other states on the dates of their admission into the Union. Governors and mayors, organized groups, libraries and schools have been asked to participate and the commission is preparing many types of material to be used in these celebrations. Representative Sol Bloom of New York is director general of the commission.

LATIN AMERICA

Congress of Physical Therapy.—The Latin American Congress of Physical Therapy, X-Ray and Radium will hold its annual convention in Guatemala City August 17-23. Those attending the congress from the United States will leave from Philadelphia on the United Fruit Liner *Castilla* August 11 and return August 30. Physicians interested in presenting papers and attending the convention may inquire of Dr. Norman E. Titus, 730 Fifth Avenue, or Dr. Cassius L. De Victoria, executive director, 1013 Lexington Avenue, New York.

Deaths in Other Countries

Sir Henry Wellcome, head of the pharmaceutical firm of Burroughs, Wellcome and Company, London, died in London, July 25, aged 82. Sir Henry was born in Wisconsin, spent his early years in Minnesota and graduated from the Philadelphia College of Pharmacy and Science in 1874. He was governing director of the Wellcome Foundation, which has maintained the Wellcome Research Institution in London, to which are affiliated the Physiological Research Laboratories, founded in 1894, the Chemical Research Laboratories, 1896, the Bureau of Scientific Research and the Historical Medical Museum, 1913, the Museum of Medical Science, 1914, and the Entomological Field Laboratories 1920.

Government Services

Use of Narcotic Drugs for Research or Instruction

Medical schools, laboratories and similar institutions using narcotic drugs in laboratories principally for research instruction and analysis are no longer to be classified under the Harrison Narcotic Act as "compounders" of narcotic drugs and subjected to an annual tax of \$24. By an amendment to the act named, approved June 22, 1936, and effective as of July 1, a person, association or corporation, not registered as an importer, manufacturer, producer or compounder but authorized by state law to obtain and use narcotic drugs in a laboratory for the purpose of research, instruction or analysis may register under a new special class of registrants, Class 6, on the payment of an annual tax of \$1.

The use of narcotic drugs for research instruction and analysis was apparently given no consideration by Congress when the Harrison Narcotic Act was passed in 1914. The Commissioner of Internal Revenue undertook to enable medical, dental, veterinary and pharmacy schools, and other scientific schools, colleges and universities, such as were using narcotic drugs primarily in experimental, analytic and research work, to obtain the necessary drugs by classifying them as "compounders" within the meaning of the act. As compounders, however, they were required to pay a federal tax of \$24 a year and to keep and to file periodically the same records required of compounders generally, which were adapted only with difficulty to the uses of the institutions named. Under the amendment to the act recently adopted, registrants in Class 6 must keep such special records relating to receipt, disposal and stock on hand of narcotics as the Commissioner of Narcotics with the approval of the Secre-

tary of the Treasury, may by regulation require. Following is the regulation with respect to record keeping.

'Special Records Required of Registrants in Class 6.—Persons who are lawfully entitled to obtain and use in a laboratory any narcotic drugs or preparations for the purpose of research, instruction or analysis, and who are registered in Class 6, are required to keep complete records relating to the receipt, disposal and stocks on hand, of all narcotic drugs and preparations. Duplicate copies of official order forms used to obtain narcotic drugs and preparations shall be retained (see Art. 70 of Regulations No. 5, as amended) and inventory on Form 713 shall be prepared, the original of which must be kept on file by the maker and the duplicate forwarded to the collector of internal revenue with the application for registration (see Art. 6 of Regulations No. 5). A special record shall be kept showing the date, kind and quantity of narcotic drug or preparation used, the particular purpose or object of such use, and of the identification and disposition of the narcotics or resulting products or residues so used, showing the date, quantity of resulting products or residues, and manner of disposition. The Government does not furnish blanks for the keeping of this record, but it should be in the following form, which lists sample items as a guide.

| | | | | Identification and Disposition of Narcotics or Resulting Products and Residues | | |
|---------------|----------------|----------|---------------------------|--|---------------|--|
| Narcotic Used | | | | Prod- ucts or Resi- dues | Quan- tity | Disposition (Destroyed Retained or Returned) |
| Date | Kind | Quantity | Purpose | Date | | |
| | The- baine | 1 oz. | Experimental synthesis | None | None | All residues de- stroyed |
| | Mor- phine | 1 oz. | Experimental synthesis | Co- daine | 1/2 oz. | Retained for in- structional ex- hibit |
| | Narco- tine | 50 gr. | Mineral analysis | None | None | Consumed in analysis |
| | Crude opium | 1 lb. | Assay | Crude opium | 1/2 lb. | Returned to registered per- son describing assay on order form No. |

"Official order forms shall be used to cover all transfers of narcotic drugs to and from registrants in Class 6, including preparations and remedies which might otherwise be exempt from this requirement under Section 6 of the Harrison Narcotic Law, as amended. Articles 65 and 106 of Regulation No. 5 are modified accordingly.

"Any product or residue resulting from the use of a narcotic drug or preparation obtained upon order form, which is desired to be retained for further research instruction or analysis, shall be placed in a container legibly labeled with the name of the narcotic drug or preparation and the date produced.

"Any sale of a narcotic drug or preparation by a registrant in Class 6 shall render him liable to registration and to payment of tax in Classes 1 or 2, as the facts may warrant, and to compliance with all other requirements of the law and regulations governing sales by registrants in Classes 1 or 2."

Dr. Williams in Charge of Quarantine Service

Dr. Charles L. Williams, senior surgeon U. S. Public Health Service and officer in charge of the Algiers Quarantine Station, New Orleans, has been promoted to assistant surgeon in the service in charge of the foreign quarantine division for the entire United States, it is reported. Dr. Williams was to have left New Orleans for Washington July 1. He will be succeeded at the Algiers station, where he has been in charge three years, by Dr. Harry E. Trimble, who has been stationed in San Francisco.

Appointed Rear Admirals

Capt. Will Melville Garton and Capt. Ulys Robert Webb were recently raised to the rank of rear admiral in the medical corps of the U. S. Navy. Captain Garton who is on duty as medical aid in the eleventh naval district, San Diego, Calif., was commissioned an assistant surgeon in the navy Aug. 5, 1898, during the Spanish-American War. Captain Webb, in command of the Naval Medical Center, Washington, D. C., was appointed in the navy Oct. 21, 1901.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 20, 1936

Health Insurance and the Voluntary Hospitals

The British Medical Association has submitted to the Voluntary Hospitals Commission an important memorandum, which shows the great changes that have taken place in the hospitals in recent years. At the beginning of the century the voluntary hospital (so called because maintained by the voluntary subscriptions of the charitable) was a place where the poor could obtain medical service, today it serves four fifths of the community, for the majority of whom it has become an agency for the provision of specialist institutional service. One cause of the change is the progress of medical science with its more elaborate methods of diagnosis and treatment, which cannot be easily obtained outside the walls of an institution and which, when they can, are extremely expensive. On the other hand, persons who attended hospitals because they could not afford to pay ordinary medical fees are now provided for by the national health insurance system (except as regards specialist services) or by provident schemes. The British Medical Association therefore thinks that the voluntary hospital should confine itself to the services which hospitals alone can provide, insisting that all its patients should obtain other necessary attention elsewhere. The outpatient department should be exclusively consultative, accepting, except in emergencies, only patients recommended to the hospital by their own physicians as requiring specialist attention.

There has long been in this country another hospital system, which has also undergone great change recently—what used to be called "the Poor Law Hospital" but is now termed the municipal hospital and has a bed capacity twice that of the voluntary hospitals. These hospitals were maintained by taxes and their medical staff was whole time and paid. They were open only to the destitute and were to a large extent infirmaries where many of the poor ended their days. Now they have become well equipped hospitals, rivaling in some ways the voluntary hospitals and they are open to all the inhabitants of the area. Those who can afford to pay are charged according to their means. The one important difference from the voluntary hospital lies in the medical staff. They are full time and paid in the municipal hospital, and their whole careers lie in its service. In the voluntary hospitals the staff work for only part of their time and are unpaid. The advantage is that the voluntary hospital is the one portal to consultant and specialist work. It also supplies the medical teachers. Thus its staff has much greater prestige than that of the municipal hospitals. Even this difference will probably diminish in time. Already the municipal hospitals have appointed paid part time consultants from the staffs of the voluntary hospitals. Though these hospitals are steadily increasing in importance the British Medical Association does not in this memorandum make any recommendation with regard to them.

REORGANIZATION OF THE VOLUNTARY HOSPITALS

It is pointed out that the majority of persons obtaining treatment at the voluntary hospitals now pay something and that the field of private practice has inevitably become contracted and consultants particularly the younger ones are finding increasing difficulty in maintaining themselves. In the view of the British Medical Association the medical staff should be remunerated for all medical service in hospitals for which payment is made directly or indirectly—by contributory scheme, local authority employer or patient. The voluntary hospital

and the municipal hospital are serving the same section of the community, and the principle of remuneration for services should apply to the two.

The small voluntary hospitals that exist all over the country away from the large cities are a different problem, as they are staffed by general practitioners. The British Medical Association holds that the importance to a general practitioner and to the efficiency of his service to the community of association with a hospital is difficult to exaggerate. There is a growing need for more extensive provision of the type of hospital in which he can treat cases falling within his sphere of competence.

The problem of the hospital outpatient has assumed considerable dimensions. The growth of the contributory scheme is responsible for the misuse of outpatient departments. The public has been slow to realize that a person is entitled to outpatient benefit only when in the view of the medical staff his condition demands it. The public has been slow to realize that the outpatient department should be complementary to and not a substitute for the medical care obtainable from private physicians. The one remedy recommended is that, except in emergency, all patients on presenting themselves at a hospital should produce an introductory letter from their own physician.

Race and Culture

The misuse of racial arguments for political purposes has caused the Royal Anthropological Institute and the Institute of Sociology to appoint a committee of anthropologists, including Sir Grafton Elliot Smith, Profs. Le Gros Clark, H. J. Fleure, J. C. Flugel, R. Ruggles Gates, J. B. S. Haldane and others to consider the racial factor in cultural development. Some difficulty was experienced in defining the term race and in the report a series of definitions by different members is given, but it was agreed that a race is composed of one or more interbreeding groups of individuals and their descendants, possessing in common a number of innate characteristics which distinguish them from other groups. In the present state of our knowledge we are dependent on physical characteristics for differentiating races. Sir Grafton Elliot Smith, chairman of the committee, observes that it is important not to fall into the common error of confusing race with nationality. The conception of race is analogous to the biologist's idea of species. A nation is a man-made assemblage of peoples, usually of various races, associated as a result of historical circumstances who in the course of time cooperate in building up a distinctive set of customs and beliefs. These become their "social heritage" not in the sense of something which they inherit in the biologic sense from their forerunners but of something which the latter have adopted, modified and handed on. National culture is stated usually to be the adoption of alien practices and ideas and their adaptation to the circumstances of the adopters at the time. It is so often assumed, particularly in the recent discussion of the Aryan question, that there is an innate tendency for certain races to develop distinctive types of culture and character which make them particularly desirable or undesirable elements of the population. There is no evidence to justify such a belief. The acquisition of culture is not due so much to innate qualities as to historical circumstances and quite arbitrary factors, though temperament may play some part in the acquisition of culture. Prof. Ruggles Gates points out that while in the past isolation was the evolutionary factor in the production of race, intermixture has largely taken its place and evolution still goes on, but in a different way.

A Diver's Ordeal

Mr. James Mearns, aged 56, a diver was working in a Scotch loch 170 feet below the surface when water entered his suit and at this high pressure paralyzed his legs. When he sent a message to the surface the men above knew that if they did not

him up slowly he would almost certainly drown and that if they pulled him up quickly he might die as a consequence of the sudden change of pressure on his body. They decided to pull him up fairly quickly, and the rapid change caused bubbles of nitrogen to form in his blood, which threatened to stop the circulation. Twice he was sent down again in another diving suit and brought up slowly in an endeavor to drive out the bubbles. But he was unable to stand the cold until these measures were successful, and it was decided to send him to University College Hospital, London. From the hospital he was sent to the premises of Siebe, Gorman & Co, submarine engineers, where he was again placed in a decompression chamber. While a careful watch was kept through the observation window, the air pressure was slowly increased until equal to that to which he was subjected when 170 feet under water. Slowly he moved his limbs about, striving to drive out the nitrogen bubbles. Six hours later the pressure was slowly reduced. He derived considerable benefit and was able to move his right leg strongly and his left a little. He was then taken back to the hospital.

The Future of Medicine in France

The recent wave of socialization of industry in France is having its influence on the medical profession. In an editorial by the secretary of the society that looks after the economic relations of the physicians of the department of the Seine, Barlerin writes that, since our ideas are subject to constant evolution, physicians should not be astonished that certain individuals are attempting to modify the manner in which medicine should be practiced. It is true that the profession should not stand still but adapt itself to the problems of the hour. One of the fundamentals of the art of healing which the profession wishes to keep intact is our independence, which permits us to utilize in our relations with patients the qualities of kindness, prudence and devotion, which are indispensable. If the physician maintains his independence, he can carry out his obligations toward the sick in a dignified and conscientious manner according to the precepts of Hippocrates. Certain political doctrines more in favor at present than at any previous epoch, have a tendency to wish to subordinate all the activities of a nation to control by the central government. Using "social progress" as a pretext, physicians would be obliged to care for the sick only at the command of state officials who have elaborated regulations which are incompetent from the medical standpoint. Now, experience in France has shown that it is the patient who suffers from making medicine subservient to bureaucrats. The protagonists of state medicine will not suffer, because they know how to escape such a maladjustment of the practice of medicine. Workers of all classes will pay for these experiments of futurist medicine by inadequate service if the medical profession does not rise up and make an organized effort to check the threatened invasion. One of the essentials on which modern medicine rests is the free choice by the sick of his or her medical attendant. This cannot exist when administrative (state) medicine requires a physician to report to the officials the diagnosis he has made in every case forbids the use of certain drugs, and last but not least limits the fees to such an extent that a great many patients must be seen every day in order that enough can be earned to support the family. It follows that very little time can be devoted to the individual case. These conditions exist already in certain public and private administrations, railroads and factories, so that when the employees of such organizations really feel the need of competent medical advice they prefer to consult a physician not connected with the respective organization, only calling on the

physician of the latter to issue a certificate allowing them to be absent from work. Many young physicians, faced with the difficulties of earning a living in private practice, regard bureaucratic medicine as a means of escape, because the hours are limited there is less individual responsibility, vacations are paid and there is a prospect of a pension on retirement. Such recent graduates have made the struggle against state medicine difficult in France. They do not understand that they are giving up their professional independence and thus are unable to give their patients the care which a personal relation without bureaucratic dictation demands.

Where Does the Money Go?

In the report made in March 1936 by the secretary of labor on the functioning of the social insurance law for 1933, some interesting figures were cited. The Parisian region (including the department of the Seine, in which Paris is situated, and four adjacent departments or counties) received about a third of the entire amount received as premiums in all of France. This third is 583 million francs (about 38 million dollars). About 54 million francs (about three and a half million dollars) was disbursed for medical care, 47 million francs for drugs and 50 million francs for hospitalization, 110 million francs was spent for loss in wages and awards for breast nursing 7,800,000 francs for medical controllers or supervisors (administrative) and 25 million francs for other costs of administration. Finally, 257 million of the total 583 million francs was placed in the reserve fund. The outlay for medical care represents only 10 per cent of the total received for premiums from employers and employees, so Drouet, in an article citing these figures and published in the *Journal de médecine* March 26 asks the question "Where does the money go?"

Some Difficulties of Social Insurance

At a recent meeting of a regional office for collection of dues from employers and workers, a speaker called attention to one of the most difficult problems which the social insurance administration in France has to meet. This is the failure of many employers to turn over to the caisses, or regional centers, the sums received from their employees as well as their own proportion of the premiums. These employers only too often utilize such funds in the conduct of their business so that, when they go into bankruptcy or are forced by judicial action to liquidate, the social insurance cards of the employees show unpaid premiums. Another difficulty is the decrease in some regions of the number of assured. In his own district this amounted to one third of those formerly insured. The increase in the number of so-called mild illnesses, for which the assured claim full compensation, has become very noticeable since unemployment has become more marked in France. This item shows five times as many claims in 1935 as in 1931, during which period the number of claims for "severe illnesses" has also risen. Whereas there is a rise in the amount of premiums paid by the employers and employees and the sums disbursed to the assured worker is decreasing, the administrative costs remain the same. Sums amounting to billions of francs have been lost on poorly selected investments of the funds held by the central bureau, which receives a certain proportion of the premiums. The fees received by the medical profession which has been most loyal in its cooperation with the social insurance authorities, account for only a minimal proportion of the funds received by the administrators of the law.

Professor Vaquez, Eminent Cardiologist, Dies

One of France's most distinguished physicians, Professor Vaquez, died in April at the age of 75 years. Up to within a few weeks of his death he took part in the meetings of the *Académie de médecine*. He had been a pupil of Potain and did not cease during his entire career to glorify the teachings

of Potain. In clinical research, Vaquez was the acme of precision and the possessor of a spirit of self criticism which he had acquired from Potain. Vaquez always seemed to be in good humor and his clinics were visited by cardiologists from all parts of the world. He was professor of clinical therapeutics, first at the Hôpital St Antoine and later at the Hôpital de la Pitié. In hematology, the work of Vaquez on polglobulism and erythremia will always be regarded as an important landmark. His contributions to cardiovascular pathology played a more important part in the development of this field of internal medicine than that of any other French clinician. His papers were translated into most of the modern languages and his reputation attracted patients from every foreign country. This homage did not alter his modesty. At medical meetings his concise and clear discussions attracted the attention of every one. He had many friends, representatives of the best in medicine, letters and arts.

May 12, 1936

Congress on Forensic Medicine

The International Congress on Forensic Medicine was held recently at Brussels.

SOCIAL MEDICINE AND FORENSIC MEDICINE

Dr Sand addressed the congress on the extent to which social medicine may be combined with legal medicine. Although certain aspects of social medicine may be profitably included within a course in legal medicine, it does not follow that all social medicine should be incorporated within the framework of legal medicine. If such were the case, other branches of medicine would be impoverished. Social medicine cannot be considered a specialty, on the contrary, it represents a synthesis, a general point of view with which neither student nor practitioner should be unfamiliar. A professor should effect an understanding with his colleagues whereby a question which clearly belongs in the province of forensic medicine or of hygiene or of clinical medicine should be left to the instructor in those subjects. On the other hand, the professor should outline the constituent elements of social medicine and point out the connection with special fields.

POSTTRAUMATIC NEUROSES

Dr Castedoat stated that posttraumatic neuroses are of many varieties. They differ from ordinary neuroses only by virtue of the circumstances under which they occur. The symptoms are similar to those of apparently spontaneous neuroses and neuroses of constitutional origin. Accordingly it is to be asked what influence, if any, the traumatism exercised. A true neurasthenia involving the entire organism can apparently be created by a shock directly affecting the nerve centers. Manifestations of hysteria do not occur subsequent to traumatism excepting among predisposed persons, but one should be loath to regard such a predisposition as a pathologic state or even as specific. It is difficult to evaluate the ingenuousness of apparently hysterical manifestations in a given case. If analysis of somatic symptoms furnishes no clue and the mental condition of the hysterical patient presents absolutely nothing characteristic, one can only resort to extramedical arguments devoid of real scientific value. Moreover, certain cases exhibit an apparent combination of good and bad faith. These considerations have influenced the development of the policy adopted by civil experts in cases of industrial accidents (grant of a small income convertible into capital) as well as that adopted by military experts in time of war (presumption in favor of the victims' good faith and abstention from imposition of dis-

ciplinary penalties). Posttraumatic neurasthenia is due, at least in some instances, to active organic lesions or to cerebral and meningeal cicatrices. In general the dysfunctions manifested are genuine and important. Emotional neurosis and psychasthenia observed following traumatism may be without exception considered as preexistent, the accident acts only to externalize and aggravate these latent conditions. Sinistrosis is not a specific disease. The term may apply to diverse mental conditions, some of which, wholly or in part, are of a pathologic nature, while others may be imputed to a bad faith bred of avarice. Thus by a veritable abuse of the term, the character of pathologic conditions may be attributed to actual simulations. Correct usage of the word "sinistrosis" is therefore not easy. Even if hysterotraumatism is no longer indemnified according to the "ready reckoners" established in 1915 for service men, indemnification continues to be granted on the basis of these tables in cases of industrial accidents. Only motivation of other than a medical nature can explain this discordance.

The Air Service in Medical Emergencies

The Royal Aero Club of Belgium announces that the emergency airplane section formed from its membership and placed under the patronage of Queen Elizabeth is soon to hold its initial meeting. The organization of this unit imposes an obligation on all. The use of the airplane in emergencies created by accident and disease has been productive of marvelous results. It has made possible the saving of human life in tens of thousands of instances in which sick or injured persons would otherwise have been condemned to certain death accompanied by much suffering. Evacuation by airplane of the sick and injured will not often be resorted to in our home country with its various transport facilities and its abundance of highly specialized hospital equipment manned by an army of physicians of the first rank. But the colony is less fortunate. There the introduction of airplane emergency service is urgently needed. In the Congo, where vast regions are deprived of all means of speedy communication, a person who does not receive necessary medical attention within twelve to eighteen hours after sustaining a serious injury is doomed. The airplane can traverse, in hours, distances that would necessitate an agonizing journey of from six to ten days by other means of transport. Regardless of cost, the colonial subjects of Belgium will be provided the best possible opportunity for medical attention.

National Prosthetic Service

Victims of industrial accidents whose condition necessitates a prosthetic appliance have heretofore received certain funds to cover the renovation, upkeep and replacement of the appliance, but there has been no advisory body to aid and guide these persons in the administration of such funds. A bureau has been set up to meet this need. Its duty will be to furnish advice to and administer the affairs of the victims of industrial accidents and other similarly disabled persons. This bureau is to be known as the "National Prosthetic Service" and it owes its creation to the minister of labor and social security. This service is to supervise the upkeep and renovation of orthopedic and prosthetic appliances issued to the victims of industrial accidents. The administration of the maintenance allowance will be confided to the bureau by the recipients. The National Prosthetic Service is directed by an administrative board composed of (a) two physicians, (b) two workers, representatives of the principal labor organizations, (c) three representatives of approved industrial accident insurance companies and (d) two representatives of the principal organized groups of persons maimed in industrial accidents. In addition two deputies of the minister of labor and social security are attached to the administrative board in the capacity of governmental commissioners.

May 30, 1936

Treatment of Empyema

In a lecture recently delivered before the Accademia Medica of Rome, Professor Stefanini reported the results of drainage between the eighth and tenth ribs, with negative pressure, in the treatment of acute postpneumonic empyema. The speaker obtained satisfactory results in thirty-six cases. The advantages of the method, in comparison with open drainage, are diminution of mortality, absence of pneumothorax, rapid expansion of the lung and early adaptation to the parietal pleura and rapid recovery.

Prof Raffaele Bastianelli stated that the criteria hitherto followed in operations for empyema frequently have been arbitrary and not based on physiopathologic principles such as are the fundamentals of constant aspiration. The results obtained in cases of general empyema especially in patients in the hospital, should be a warning to avoid performance of open drainage in total empyema. Open drainage in these cases may result in development of secondary infection and fistulas. The speaker advised a small incision in thoracotomy, making the following steps, whenever possible, with a negative pressure. In cases of general empyema, aspiration is the preferable treatment. He stated that the incision over the fourth and fifth ribs, between the two axillary lines, is preferable to the lower incision, because the former prevents the formation of thoracic fistula whereas in the latter the diaphragm, during elevation, may come in contact with the drainage tube and disturb the free elimination of the exudates.

Professor Chiasserini showed his preference for the use of a rubber tube in the drainage, instead of using Pezzet's drainage. A drainage with a valve is not to be used in putrid empyema.

Professor Egidi did not share the optimistic opinions of his colleagues. Aspiration has been known in hospitals for a long time and its failure to achieve popularity shows that its results are not satisfactory. The maintenance of negative pleural pressure establishes favorable conditions for respiration and also for the return of normal expansion of the lung.

Aspiration of the secretions and lavage of the pleural cavity are useful means of controlling sepsis. But, according to the speaker, this type of treatment is similar to the closed one, both of which are insufficient. In some cases of putrid empyema the fibrin masses block the tubes and sepsis extends to the thoracic wall. The expansion of the lung can be obtained by bronchial hyperpressure as well as by pleural hypopressure. Bronchial hyperpressure does not prevent the treatment of pleural sepsis and can be produced by simple, although not perfect means.

Professor Alessandrini supported Dr Stefanini's method. The use of drainage with negative pressure reduces the duration of the treatment and gives better results than aspiration under positive pressure. Stefanini said that the drainage from the fourth to the sixth space is insufficient to permit complete elimination of the exudates when aspiration of about 50 cm. of a water column is used. The speaker did not agree on the use of a large incision in the pleura because of the difficulties presented during pleural suture.

Chronic Appendicitis

Professor Tramontini, in a lecture recently delivered before the Società di Scienze Mediche di Conegliano e Vittorio Veneto, discussed chronic appendicitis the existence of which is admitted by some surgeons and authors and denied by others. From a medical point of view it cannot be denied since Leotta and his pupils of the Bari University systematized the disease in the complicated syndrome of the right abdomen. The disease does not represent acute appendicitis in miniature with typical symptoms and muscular defense, but it has its proper picture as a

form of chronic intestinal or gastric dyspepsia. At operation, more or less strong adhesions and inflammatory conditions of the appendix, ecchymotic points and canalicular suppuration may be found, or else perivisceritis of a type of membranous pericollitis with remote reactions on the upper crossway (duodenum and pylorus) can be observed. Frequently dyspepsia produces pain, with an eccentric painful point, metabolic disturbances occur and the patient becomes emaciated. The diagnosis is made by the roentgen examination by which, six hours after ingestion of the opaque meal, peristalsis and spasm of the cecum and of the ileum are seen at a point in the internal border of the cecum. Medical treatment fails in producing a cure of the condition. A treatment by sedatives, aiming to calm the painful reflexes, is administered before the operation, which should be performed only during a period of amelioration of the symptoms.

Society News

At a recent meeting of the Società di Dermatologia e Sifilografia of Padua, Professor Fiocco spoke on chronic keratotic dermatitis of the hands which affects workers in the broom industry. The disease is due to trauma of the hands by the stems of the plant. It is characterized by erythema, hyperkeratosis and formation of fissures on the hands. The subjective symptoms are a sense of local warmth, pruritus and pain. The prognosis is good.

Professor Freund reported a case of scrotopenile elephantiasis from inguinal lymphogranuloma. The diagnosis was made by the Frei test, twelve years after onset of the disease. Formerly the disease consisted of inguinal buboes without any primary lesion. A radical operation then seemed to have resulted in cure, but a large tumefaction recurred on the penis and scrotum a few months later. The speaker emphasized the importance of an early Frei test in suspected cases of inguinal lymphogranuloma in order to administer treatment early and thus prevent serious complications.

Professor Levi, from his experience in a dispensary for the treatment of venereal disease, said that nonrecognized syphilis is frequent and is often transmitted to the family and the offspring. The speaker advised the organization of special departments for treating syphilitic persons in whom a diagnosis has not been previously made.

Professor Ravalico reported satisfactory results from intramuscular injections of strychnine, without association with any other treatment, in gonorrheal vulvovaginitis in little girls.

RIO DE JANEIRO

(From Our Regular Correspondent)

June 15, 1936

Control of Narcotics

The government of Brazil has entered the international committee for controlling and supervising the traffic of narcotics. The Brazilian committee consists of Mr J S da Fonseca Hermes, foreign minister, and Drs João de Barros Barreto, director of public health and social service, Roderyal Cordeiro de Farias, inspector of medical practice, Rubens M de Figueiredo, procurator of the department of national education and public health, Democrito de Almeida, substitute delegate for the federal district, Pedro Pernambuco Jr, head of the Botafogo Sanatorium, Maria Saraiva, head of the institute for clinical teaching, and J Soares Brandão and Edison Pitombo Cavalcanti, representatives from the ministerial offices of justice and labor.

Anniversary of Instituto Oswaldo Cruz

Ceremonies were held at the Instituto Oswaldo Cruz of Mangueiras May 7, to celebrate the thirty-sixth anniversary of the foundation of the institute. Dr Cardoso Fontes, director of the institute made speeches in memory of Baron de Pedro Afonso, founder of the institute in 1898. Some cases of bubonic plague developed in Rio de Janeiro in 1898 and the Baron de

Pedro Affonso, with the collaboration of Oswaldo Cruz, Figueiredo Vasconcellos, Ismael da Rocha and Henrique de Toledo Dodisworth as well as of the government, went to Europe and came back with the necessary equipment for production of antiplague serums and vaccines in this country. From that time to the present the work of the institute has been valuable. During the ceremonies, a bust of Baron de Pedro Affonso was unveiled in the central hall.

Treatment of Shock by Acacia Solution

Dr. Eduardo Etzel, in a recent lecture, reviewed theories on the mechanism of production of shock and emphasized the important role of nervous disorders and hemorrhages in the production of shock. There is a difference between hypotension and shock in hemorrhage. The former is controlled by intravenous injections of sodium chloride solutions, whereas the latter requires morphine to control the nervous condition, tonics for improving vascular derangements, cardiac stimulants and heat. The treatment directed to control the failing circulation consists in injections of a 6 per cent acacia solution in a 9 per cent sodium chloride solution. The speaker administered acacia injections to eighty patients who were suffering from shock and obtained recovery from postoperative, obstetric and hemorrhagic shock respectively in 86 per cent, 100 per cent and 90 per cent of the cases. Toxic and traumatic shock are little influenced by the injections of acacia solution. It is advisable to give the injections early in the production of shock. Its action is mechanical.

Hospital for Children

The São Zacharias Hospital, located at avenida Carlos Peixoto and Botafogo in Rio de Janeiro, will open in the near future for the care of children of poor families. Dr. Calazans Luz has been appointed head of the hospital, which is a modern four story building with 230 beds.

X-Ray Department Opened

A department for x-ray work was recently opened at the Botafogo Polyclinic in Rio de Janeiro. The expense of constructing the pavilion and of buying the x-ray apparatus was met with donations. Dr. Victor Cortes has been appointed director of the department.

JAPAN

(From Our Regular Correspondent)

June 15, 1936

Sterility Among Japanese Women

At the thirty-fourth meeting of the Gynecologic Society of Japan, Dr. T. Shinoda of Tokyo Imperial University read a paper on the etiology and treatment of sterility. In his paper, which contained numerous statistics, he said that in the five years ended in December 1935 he had in the university hospital 1,211 women patients with primary sterility and 706 women with secondary sterility. He found that the pregnancy rate in the first year of marriage in this group was 67.9 per cent, in the second year of marriage, 40.5 per cent, in the third year, 18.7 per cent, in the fourth, 12.9 per cent, in the fifth, 8.8 per cent, in the sixth, 4.1 per cent, in the tenth, 0.7 per cent, and in the twentieth 0.1 per cent. Ninety per cent of the cause lay in women who have never conceived and between 2 and 3 per cent of sterility was found when both the husband and the wife were healthy. The chief causes seemed to be inflammatory troubles among 1,211 cases. 82.8 per cent of the women were suffering from inflammation mostly caused by gonorrhea, but in not a few cases caused by tuberculosis. Simple endometritis, catarrh of the cervix, retroflexion of the uterus, and irregularity of menstruation may cause sterility but there is nevertheless a great possibility of conception. Hystero-graphy that is taking a roentgenogram after the injection of iodized

oil into the fallopian tubes, is not only necessary for diagnosis but is highly effective also as a method of treatment. In this group of cases, forty-two women became pregnant within several months merely by this means without any other direct treatment. Besides this, examination of the endometrium and the microscopic examination of the husband's semen are essential to determine the cause of sterility. Nothing is more difficult than the diagnosis and treatment of sterility, at least these three measures must be employed.

The Leprosy Campaign

Dr. M. Miyagawa reported at the general meeting of the Japan Leprosy Association to the effect that the campaign against leprosy in this country has now entered the period of activity, having left the period of investigation behind. This is clearly shown in the increased number of antileprosy societies which sympathize with the lepers. An unsolved problem is that of finding out the exact number of lepers in this country. Five official investigations have been made by the home office since 1904, and according to these the number of lepers has considerably decreased. But the official reports cannot be said to be correct, for many cases are supposed to be concealed. At any rate the official number is reported as follows: 1904, 30,357; 1906, 23,851; 1919, 16,261; 1925, 15,351; 1930, 14,741; 1935, 15,274. Reports, however, made by Dr. M. Murata give entirely different figures. He says there are 109 lepers per thousand of population, which means that there are over 62,000 lepers here. He insists that leprosy has never decreased but is on the increase. The office knows that what it announced was not correct and believes the true number to be about 17,000. There are eight government and public and seven private leprosy sanatoriums. These fifteen can accommodate 5,938 lepers. Within the coming five years 10,000 beds are expected to be given over to the lepers, for the Leprosy Prevention Association, which was organized in 1930, is going to become active. One petition was filed with the government that a special prison for leper criminals should be built. The leprosy campaign is seen on all sides throughout the country.

Outbreak of Rice-Cake Poisoning

May 10 the rice-cakes which are stuffed with bean jam (called "daifuku" or great happiness) were given to 1041 pupils of the Hamamatsu Middle School in Shizuoka Prefecture after the athletic meeting was over on that day. Each pupil received six cakes. Of those who ate the cakes, 2,500 pupils and their family members fell sick on the next day with vomiting, diarrhea, pain in the abdomen, pain in the chest and a temperature of 38 to 39 C (100.4 to 102.2 F). Within a few days forty-three patients were dead and ninety-four others were still in a serious condition. Forty doctors were hurriedly dispatched to the scene to aid the practitioners in that city. The real cause is not officially reported, but it is believed to be in the bean jam, which easily becomes contaminated.

Medical Graduates

The number of graduates this year from seven medical departments of imperial universities, twelve medical universities and fourteen medical colleges, public or private, was 322, including 397 women graduates. This number is only twenty-four less than last year, but when compared with 1930 it is 1,047 larger. The oversupply of physicians in the near future is much discussed in medical circles.

Takayama Elected President of University

Dr. Masawo Takayama, president of Nagasaki Medical College has been elected president of the Kyushu Imperial University. He was born in Tokyo in 1871 and is a graduate of the Tokyo Imperial University. In 1900 he went to Germany to study medicine staying about six years. Three medical men are now presidents of the imperial universities.

Marriages

EPPIE CHARLES POWELL JR., Rocky Mount, N C, to Miss Eleanor L Bizzell of Goldsboro, July 1, in New York

PHILLIP AUGUSTUS DEGNAN, Waynesboro, Pa, to Miss Eva Mae Riehl of Washington, D C., May 11

CARL WILLIAM IULER, Columbus, Ohio, to Miss Mildred McKee Blair in Ashland, Ky, in May

JAMES ROBERT LYMAN, Hartford, Conn., to Miss Charlotte Cox Litchfield of Westport, May 30

WILLIAM M MOUNT, Rochester, Minn, to Miss Muriel Millet of Indianapolis, May 5

JULIUS L GOLDENBERG to Miss Bernice Chutkow, both of Los Angeles, recently

HOWARD R CAMPBELL to Miss Dorothy Schaffer, both of Dayton, Ohio, in May

THOMAS HALE HAM to Miss Fanny Chapin Curtis, both of Boston, May 16

GEORGE J HOGGEN to DR MARGARET M LODER, both of Rye, N Y, May 12

Deaths

Charles Harrison Frazier of Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1892 Chairman of the Section on Surgery of the American Medical Association from 1913 to 1914, professor of clinical surgery from 1900 to 1922, dean from 1902 to 1909, and since 1922 John Rhea Barton professor of surgery at his alma mater, professor of neurosurgery at the graduate school of medicine, during the World War was consultant in neurosurgery to the Surgeon General of the U S Army, and in 1920 represented the Surgeon General as a member of the Interallied Surgical Conference in Paris, member of the American Surgical Association Society of Clinical Surgery, Society of Neurological Surgeons and the Association for Research in Nervous and Mental Disease, member and past president of the American Neurological Association, fellow of the American College of Surgeons, in 1933 was made a member of the German Academy of Natural Sciences, in 1913 a founder and for many years president of the Public Charities Association of Pennsylvania, surgeon in chief of the Hospital of the University of Pennsylvania, member of the board of trustees of the University of Pennsylvania, author of numerous scientific articles, aged 66, died, July 26, at his summer home in North Haven, Maine.

Carl Theodor Gramm, Downers Grove, Ill College of Physicians and Surgeons, Keokuk, Iowa, 1893, member of the Illinois State Medical Society, also a dentist, at one time held the chair of dental and oral surgery and pathology at his alma mater, treasurer, professor of stomatology and histology and director of the biological laboratories of the Illinois College of Medicine, Chicago formerly connected with the dispensaries of the United Hebrew Charities and St. Joseph's Hospital, aged 74, died June 30, in the Edgewater Hospital Chicago, of carcinoma of the bladder

Carroll Fox of Medical Director, U S Public Health Service, Staten Island N Y, University of Pennsylvania Department of Medicine, Philadelphia, 1897 chief officer of the U S Quarantine Station at Rosebank, entered the public health service as an assistant surgeon in 1899, was promoted to passed assistant surgeon in 1904, surgeon in 1913 and medical director in 1930 was sanitary adviser to the navy during the World War aged 61, died, May 24 in the U S Marine Hospital Stapleton, of coronary thrombosis

William Allan Claxton, Jacksonville, Fla, Queen's University Faculty of Medicine, Kingston Ont., Canada, 1909 member of the Florida Medical Association served during the World War, at one time health officer of Morgan County, Fla and Miami and superintendent of the Oak Lawn Sanatorium Jacksonville, formerly district health officer and tuberculosis clinician state board of health of Florida aged 51, died May 21, in the Veterans Administration Facility, Oteen, N C., of pulmonary tuberculosis

Arthur Jacob Wolff, Hartford Conn., Texas Medical College and Hospital Galveston 1876 Bellevue Hospital Medical College New York, 1883, member of the Connecticut State Medical Society for many years bacteriologist for the city health department and member of the state board of health

formerly on the staffs of the Mount Sinai Hospital and St Francis Hospital, aged 81, died, June 22, of carcinoma of the colon

Samuel Ravaud Benedict of Birmingham, Ala., University College of Medicine, Richmond, Va, 1908, fellow of the American College of Surgeons, attending surgeon to St Vincent's Hospital, chief surgeon to the Alabama Power Company, district surgeon to the Illinois Central Railroad and surgeon to the Mobile and Ohio Railroad and Pullman Company, aged 53, died, May 10, in a hospital at Baltimore, of splenomegalia

Oscar Evald Olson, Red Oak, Iowa, University of Nebraska College of Medicine Omaha, 1921 member of the Iowa State Medical Society, formerly secretary of the Montgomery County Medical Society served during the World War, on the staff of the Murphy Memorial Hospital, aged 44, died, May 5, in the Jennie Edmundson Memorial Hospital, Council Bluffs, of scarlet fever

George Tilton Doolittle, Spokane, Wash, Yale College Medical Department New Haven, Conn, 1884, member of the Washington State Medical Association, formerly member of the board of health, city health officer, member of the state legislature and city council for many years on the staff of the Sacred Heart Hospital, aged 75, died, May 2 of erysipelas

Thomas Eli Anderson, Statesville, N C, Jefferson Medical College of Philadelphia, 1878, member and past president of the Medical Society of the State of North Carolina formerly secretary and member of the state board of medical examiners, for many years a member of the state board of health and at one time secretary and vice president, aged 84, died, May 19, of acute nephritis

Robert Lee Gardner, Chesterfield S C, Atlanta (Ga) School of Medicine, 1909 member of the South Carolina Medical Association past president and secretary of the Chesterfield County Medical Society member of the board of trustees of the school district and health officer, served during the World War, aged 50, died, May 5, in the McLeod Infirmary, Florence, of pneumonia

Matthew Cushing O'Brien of Philadelphia Temple University School of Medicine, Philadelphia, 1908, served during the World War for many years physical director in public schools, formerly demonstrator of anatomy and clinical surgery and instructor in chemistry at his alma mater aged 63, died, May 22, in the Temple University Hospital, of rupture of the heart

James Harvey Paul, Jamesville, N Y, Queen's University Faculty of Medicine, Kingston, Ont Canada 1898, president of the village board of education health officer of the town of De Witt physician to the Onondaga Penitentiary, on the staff of the Crouse-Irving Hospital, Syracuse, aged 62, died, May 10 of coronary thrombosis

James Clinton Hawkins of Blackwell, Okla Washington University School of Medicine St Louis, 1910, past president and secretary of the Kay County Medical Society, on the staff of the Blackwell Hospital aged 52 died in May, in a hospital at Weaubleau, Mo, of injuries received in an automobile accident

Horace Martin Evans, Indianapolis, Northwestern University Medical School Chicago 1892 member of the state industrial board, formerly president of the Valparaiso (Ind) University and bank president, served during the World War, aged 76, died, May 12, of coronary occlusion

John Milton Fouts, Richmond, Ind, Central College of Physicians and Surgeons, Indianapolis 1898 member of the Indiana State Medical Association formerly county health officer, on the staff of the Reid Memorial Hospital, aged 64, died May 10 of coronary thrombosis

Lawrence Edward Coen, Clifton N J, Long Island College Hospital Brooklyn 1910, for many years school and city physician, on the staffs of St. Joseph's Hospital Paterson and the Passaic (N J) General Hospital, aged 48, died, May 12, of coronary thrombosis

Francis De Revere, Staten Island N Y, College of Physicians and Surgeons Medical Department of Columbia College New York, 1888 for many years diagnostician for the health departments of the city of New York and Staten Island aged 71 died May 12

Frank McCollum Cox, Chicago, Hering Medical College, Chicago, 1901 College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1909 aged 59, died May 8 in the Augustana Hospital, of myocarditis

James M Freeman, Lavonia Ga Georgia College of Eclectic Medicine and Surgery Atlanta, 1893 member of the

Medical Association of Georgia, aged 67, died, May 16, in a hospital at Royston, of acute intestinal obstruction

Simon Francis Curran ☉ Boston, Tufts College Medical School, Boston, 1902, past president of the Norfolk District Medical Society, served during the World War, aged 61, died, May 19, of carcinoma of the sigmoid and rectum

Robert Russell Bridges ☉ Scottsboro, Ala., Vanderbilt University School of Medicine, Nashville, Tenn. 1913, past president and secretary of the Jackson County Medical Society, aged 47, died May 16, of mitral stenosis

Reuben Taylor Harrod, Oktaha, Okla., University of Tennessee College of Medicine, Nashville, 1891, member of the Oklahoma State Medical Association, aged 68, died, May 18, of carcinoma of the head of pancreas

Andie Cleon Calvert, Italy, Texas (registered by Texas State Board of Medical Examiners under the Act of 1907), member of the State Medical Association of Texas, aged 53, was drowned while fishing, May 5

Correspondence

"LEUKEMIA WITH THROMBOCYTOSIS"

To the Editor—In THE JOURNAL, May 23, appeared a communication entitled "Leukemia or Polycythemia," from Dr. William Dameshek, in which he expressed the opinion that my case report entitled "Leukemia with Thrombocytosis" should have been labeled polycythemia

I was greatly interested in Dr. Dameshek's opinion. I sent him a blood smear of the patient in question and was pleased to receive a reply from him in which he said in part "I am rather sorry that I took exception to your diagnosis of leukemia, but I did feel that I wanted to bring out the fact that polycythemia is really not entirely a red cell disease but one in which in certain cases the white cells or the platelets are very much more involved than are the red cells. You are undoubtedly familiar with the cases of polycythemia which in the course of time have become pretty typical examples of myelogenous leukemia. Whether or not it is possible to distinguish one situation from the other in the process of transition is questionable."

It is my opinion that my case is just such a one as he mentions—one suggesting a polycythemia clinically although the red cells never exceeded 5,800,000 but in the course of observation presented the blood picture of a leukemia with stem cells and leukoblasts

Before reporting the case a smear was submitted to Dr. Hal Downey of the University of Minnesota and he concurred in the diagnosis of leukemia. He makes the point after seeing the report of a more recent examination of a blood smear in this case, taken May 5, 1936, that stem cells, leukoblasts and promyelocytes are not expected in ordinary cases of polycythemia. He also calls attention to the fact that myelogenous leukemia may be a "panmyelosis," or only one line of the myeloid system may be involved, in my case apparently the megakaryocytes primarily. CARL B. DRAKE, M.D., St. Paul.

TREATMENT OF ACID BURNS OF THE EYE

To the Editor—New textbooks on the eye continue to advise neutralization of acid burns of the eye with weak alkaline solutions and neutralization of alkali burns of the eye with weak acids

In an experimental study by C. K. Cosgrove and W. B. Hubbard (Acid and Alkali Burns of the Eye, an Experimental Study, *Ann. Surg.* 87:89 [Jan.] 1928) it was found that the proper treatment of acid and alkali burns of the eye was immediate thorough dilution by irrigation, other types of treatment being contraindicated or unimportant.

The experiments were carried out on a large group of rat and rabbit eyes. (Some of the animals on which the experiments were being conducted and the results were exhibited at the meeting of the American College of Surgeons in Detroit, and later the results were demonstrated with pictures and slides before the National Safety Council at Chicago.)

Our experiments agreed with the study of Davidson, who showed conclusively that the intensity of an acid or alkali burn of the skin is increased by the use of a neutralizing agent and demonstrated that dilution was more effective than neutralization as a first aid method

In our experiments we found that immediate dilution by irrigation was of paramount importance. Water, being abundant, is the proper fluid for irrigating. Speed in the removal of the chemical is absolutely necessary as the extent of the injury depends on the length of time the chemical has acted. We found that neutralization without irrigation is absolutely contraindicated. Thorough irrigation immediately with a re-

tralizing fluid in preference to water is of questionable value and is not practicable. Neutralization after irrigation with water had no important effect in our cases.

A possible explanation of our observations follows. Attempted neutralization with a weak solution without irrigation does not adequately neutralize the offending chemical, and it would be illogical to use a very strong neutralizing fluid. Neutralization after irrigation is not of great importance. In an eye that has been burned by an acid and has had treatment by immediate irrigation, one of two conditions exists. Either there is no free acid present or free acid is present in extreme dilution and unimportant. The base of the ulcer is covered by an insoluble acid proteinate. The addition of weak alkali may now dissolve this proteinate and react with the exposed cells to cause some further injury. In case of an alkali burn the proteinate is soluble and the alkali tends to withdraw water from the cells. These two actions of an alkali probably account for the fact that alkali burns are more severe than acid burns. Addition of a weak acid would have a tendency to form an insoluble proteinate and prevent further removal of water from exposed cells, and thus possibly do some good. Since, however, all excess alkali has been removed by irrigation, such treatment would be of little importance. The production of heat and of salts and new inorganic acids and alkalis when an attempt is made to neutralize may cause some further injury in an eye burned by an acid or an alkali.

Let me stress that immediate removal is the treatment of first importance after acid and alkali burns of the eye. Neutralization without removal is improper treatment. The most that can be said for the use of weak neutralizing substances after removal is that it may do a little good after alkali burns and may do some harm after acid burns.

W B HUBBARD, M D, Flint, Mich

COEXISTENCE OF DIPHTHERIA AND SCARLET FEVER

To the Editor—With regard to the incidence of the coexistence of diphtheria and scarlet fever the wide divergence in opinions of Levinsohn in *THE JOURNAL*, June 27, page 2253, and of Zabin in the May 2 issue, page 1588 can be accounted for only by an apparent misunderstanding in evaluating the diagnosis. A diagnosis of concomitance of the two infections is not always easily made even by one having an extensive experience. One must bear in mind that the finding of diphtheria organisms in the throat confirms but one thing, namely, that the organisms are present. They may be virulent or avirulent and both are found in carriers. Then, if the organisms present are found to be virulent, the clinical picture also must be present to complete the diagnosis. Using these criteria, which are the only tenable ones, for a diagnosis, the coexistence of these diseases is found to be rather uncommon in the first week of the scarlet fever infection. I was much interested in this problem when actively associated with Willard Parker Hospital, New York, from 1928 to 1932, during which period I found this picture occurring only four times in 5,000 cases of scarlet fever. However, the incidence of diphtheria in the convalescent stage is more common and the reason was shown in the work of Kojis and Craig (*Am J Dis Child* 49:383 [Feb] 1935).

With regard to the statement that diphtheria occurs in negative Schick individuals it should be emphasized that because an individual was Schick negative at one time does not mean that he will remain so for all future time. The significance of this is appreciated when one considers that the fluctuation of diphtheria antitoxin in the blood is definitely influenced by different factors and conditions which are described in the reference cited.

FERDINAND G KOJIS M D New York

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

PREMATURE BALDNESS

To the Editor—I have under my care a youth aged 18 years a college student, who for the last year has been losing his hair. There is no dandruff. His scalp is dry. His general condition is good except for a chronic nasal pharyngeal infection. He had his tonsils removed nine years ago and a septum operation two years ago. He spends his summers at camp in the open air and gets a good nutritious mixed diet. His father and uncle lost their hair around 30 years of age. There is no apparent endocrine disturbance. He belongs to the thyroid type of individual. He has tried the usual massage and antiseptic lotions without any effect. Is the boy doomed to early baldness or can it be prevented? Can you suggest any medication or literature that I may look up on the subject? Please omit name. M D New York.

ANSWER—The early onset of the alopecia with paternal heredity in a man in an intellectual pursuit gives a gloomy prognosis for salvation of the hair. Every effort should be made, however, to save what hair is now left. The combings of two days should be counted in two parts, those over two inches and those shorter. If the hair is very short at present this may not be helpful, but under ordinary conditions the prognosis can be estimated by the proportion between long and short hairs that are being lost, as well as by the total number of hairs lost each day. From thirty to forty hairs daily is a normal loss. Short hairs should not exceed a fifth of the long ones. Repetition of the count at intervals of a month will give information as to the success or failure of treatment.

The general health should be kept at the highest possible plane. Overwork, particularly mental, or overplay and bad hours should be avoided. A light, soft hat or none at all should be worn. He should not wet his scalp daily in order to comb his hair easily but should brush the dry hair vigorously for ten minutes once a day and massage in the ointment or lotion at another time for ten minutes.

An ointment of salicylic acid 3 per cent, sulfur and liquor carbonis coal tar solution N F, of each 5 per cent in rose water ointment, is a good one to begin with until the loss of hair is checked. If stronger measures are desired, lactic acid from 10 to 20 per cent in 50 per cent alcohol may be rubbed on every third day or oftener until the scalp is red. There are many formulas for ointments and lotions. Treatment is discussed by

Jackson and McMurtry *Diseases of the Hair* Philadelphia Lea & Febiger, 1912
Ormsby O S *Diseases of the Skin* Philadelphia Lea & Febiger 1934
Sutton, R L and Sutton R L, Jr *Diseases of the Skin* St. Louis, C V Mosby Company 1935

Ultraviolet therapy has probably been tried already but can be repeated after the tanning effect has worn off. It is helpful, particularly if given vigorously to cause a definite sunburn.

DESTRUCTION OF INTERVERTEBRAL DISKS

To the Editor—A patient complained of pain in the back and on roentgen examination a diagnosis of destruction of the intervertebral disks was made. The patient states that he was struck on the head about one year ago and that since that time the back has been hurting. At present he is in a body cast with slight hyperextension. Please give me your opinion as to the etiology with regard to trauma and further treatment of this type of case. Please omit name. M D Pennsylvania.

ANSWER—The intervertebral disks are frequently injured by traumatism. In some cases the nucleus pulposus may be forced through its enveloping annulus fibrosus and into the substance of the body of the vertebra immediately above or below. In milder cases, tears in the wall of the annulus may lead to desiccation or absorption of the disk. Calcification of the nucleus may occur, usually after long-continued mild traumatism.

The disks are rapidly destroyed in cases of tuberculosis of the spine, and on the other hand, are quite resistant to malignant metastasis. This is one of the important signs in the differential diagnosis between these two conditions.

If the destruction in the present patient is at or below the seventh dorsal vertebra a plaster-of-paris body cast or a Taylor back brace will give efficient support which must be continued for at least three months. The spine should be held in marked hyperextension to relieve the pressure on the damaged disks and to facilitate a possible regeneration of the disks.

If roentgen examination at this time shows no regeneration, a mild kyphosis will gradually develop in spite of conservative treatment. Pain may appear in the nerve roots, because of the diminution in size of the foramina through which the roots emerge, owing to the collapse of the disk and the consequent overlapping of the articular facets.

When severe pain and marked kyphosis are present, it might be advisable to perform a spinal fusion operation, to produce a bony ankylosis of the vertebrae in the region involved. This can be done safely and satisfactorily by the Albee or the Hibbs technic or preferably by a combination of the two methods.

In most cases, prolonged protection by a brace or a body cast will afford sufficiently good results.

SEX FUNCTION AFTER PROSTATECTOMY

To the Editor—In the matter of prostatectomy it strikes me as very strange that little or nothing ever appears in the literature regarding its effect on the sexual function nor can much definite information be elicited on this point by inquiry among surgeons of my acquaintance of considerable experience in this line. An active man of 64 in excellent physical condition with undiminished sexual libido and power having experienced no discomfort save some diminution in the force of the stream in voiding is suddenly seized after a hard day's work with a chill and an acute cystitis, the symptoms continuing several days with pus and considerable free blood in the urine. Consultation and examination by a surgeon disclosed a moderate enlargement of the prostate and operation was advised which was accordingly performed—the usual two stage operation. This was four years ago. The man is still strong and active as ever in his profession but has ever since been sterile and practically impotent sexually. Erection is imperfect if orgasm occurs it is feeble and there is no ejaculation. I should like to know whether this is the common experience in such a case and if so whether the operation of transurethral section now considerably in vogue is followed by the same destruction of the sexual function. It seems to me that in certain cases this phase of the subject is deserving of more consideration than it receives. Please omit name.

M D Massachusetts

ANSWER.—The effect of prostatectomy on sexual function has been referred to in a number of articles on treatment of the prostate gland and in textbooks on genito-urinary diseases. It is generally recognized that there may be a distinct diminution and loss of this function following prostatectomy.

It has been claimed that the function of the verumontanum and the ejaculatory ducts is maintained more fully following perineal prostatectomy than suprapubic prostatectomy. However, this is disputed by the adherents of the latter method.

The exact cause for this loss of function is a matter of contention and doubtless the factors involved are variable. In some cases function returns in the course of time and is due to loss of strength and vitality consequent to operation. In other cases the imagination plays a large part and any changes noted are largely on a functional basis. That an organic lesion may follow the operation, however, which will affect the condition, is undoubtedly true. One of the advantages of transurethral prostatic resection is that loss of sexual function is caused in a comparatively small percentage of cases. This would substantiate the argument that trauma to the ejaculatory ducts and the verumontanum is undoubtedly a factor in causing these symptoms, since such trauma is largely obviated by transurethral resection.

No treatment other than treatment of residual prostatic infection has had any appreciable effect on this condition.

TENDERNESS OVER AORTA

To the Editor—I frequently see patients in whom while doing a gastro-intestinal examination I find nothing abnormal with the exception of marked tenderness on deep palpation over the spine or the abdominal aorta. I have been unable to find any reference to the significance of this observation.

M D Michigan

ANSWER.—The tender aorta particularly in women who have borne many children and have a flabby abdominal wall is well known to the experienced clinician. Among the Mexican women of the Southwest it is sometimes the main complaint. At first sight it would seem that this should be due to an arteritis of some kind and in some persons this may be the case. Somewhat against this view is the fact that very often the pathologist finds at necropsy a badly ulcerated abdominal aorta or in other cases the roentgenologist sees the tube outlined by calcified plaques and yet the patient will not have complained of pain in the abdomen. In many women it may be that the aorta is tender just as many other tissues of the body are exquisitely but unaccountably tender.

There doesn't seem to be any definite treatment for the disease. Fortunately in most cases the woman can put up with the pain if she can be assured that many others have had it

without coming to any bad and early end. Iodides might be tried in small doses and perhaps theobromine. Most helpful probably would be a regimen of rest and sedatives that would serve to lower the general level of hyperesthesia and to raise thresholds of sensation.

DERMATITIS

To the Editor—My wife has been troubled for some years by a punctate rash in the fold at the bend of the elbow. It is about 3 inches in diameter and is located on both arms. The rash is bright red and does not itch but it is not desirable for cosmetic reasons. It seems worse at times and then almost suddenly disappears. It is present during the summer when sleeveless dresses are worn as well as during the winter months. There is no rash on any portion of the body and the general health is excellent. No drugs are used over long periods of time. Lotions and greasy ointments made the condition worse. A gauze bandage over the arm seems to help more than anything else. Please omit name and thank you.

M D New Hampshire

ANSWER.—The fact that the eruption is bright red is of variable acuity, disappears suddenly, and is relieved when the part is protected by a gauze bandage over the arm suggests the likelihood that the condition is dependent on some external factor for its exciting cause. External irritant contacts should be carefully ruled out, such as strong soaps, perfumes (which are sometimes applied in these areas) and dyes that may be present in garments that were worn. In most of these eruptions, however, there is usually some associated itching and burning, and vesicles are often present.

Neurodermatitis must also be given consideration but in this condition there is more of a tendency toward the development of lichenification with grayish or brownish discoloration of the skin. Associated lesions are also usually present in the popliteal spaces and on the neck, face and chest.

Scrapings from the surface should be examined to rule out the possibility of an atypical fungous infection, and the urine should be examined for sugar.

Treatment should consist of the continuation of a protective bandage, a low carbohydrate diet, the avoidance of external irritant contacts, the use of bland soaps, and bland local applications. In view of the fact that greasy ointments are not well tolerated, wet dressings of aluminum subacetate solution 1:16 may be employed. Cautious unfiltered x-ray therapy, from 50 to 75 roentgens weekly for four to six doses may prove beneficial.

SYPHILIS AND HEART DISEASE

To the Editor—A man aged 47 had attacks of dizziness about fifteen years ago. The Wassermann reaction is positive. He was treated four years and the Wassermann reaction has been negative since. About six months ago the patient felt as though an electrical shock was running from the buttocks down the legs into the arms and wrists and he had a peculiar feeling in his head. There was slight pain around the heart. These feelings come on early in the morning while he is sitting in a chair and pass off and return about 10 or 11 o'clock. After lunch the patient feels good then again when he goes to bed the feelings return but pass off. After ascending stairs and doing laborious work he has the feelings almost every day. There is a slight aortic murmur. The reaction is negative for sugar and albumin. The blood pressure is 136 systolic, 70 diastolic. He has the same feeling next day after too much indulgence in alcohol and at times after a full meal and when walking on the street. Please suggest diagnosis and treatment. Omit name and address.

M D Connecticut

ANSWER.—Since the patient has had syphilis, a reinvestigation of his status with regard to this disease is indicated even though there has been a Wassermann reversal on his blood. All the symptoms listed may be on a syphilitic basis. The electrical shocklike sensations extending down the arms and legs suggest a variant of the lightning pains of tabes dorsalis in which it is common enough to find a negative blood Wassermann reaction. No mention is made of neurologic examinations. Proper examination should decide this question. In the event that the results of physical examination are not conclusive examinations of the spinal fluid, including serologic tests, should be made.

The precordial pain in association with the other symptoms coming on after effort, after a full meal or after the consumption of large amounts of fluid is especially significant. This type of pain, much more characteristic of the syndrome of angina pectoris may be present in syphilitic aortitis. The aortic systolic murmur might be accounted for either on the basis of aortitis with aortic dilatation or on the presence of atheromatous degenerative changes in the ascending portion of the arch of the aorta. Other neurologic disorders might be considered even cord tumor which would be located rather high if symptoms are to include the arms. However in the absence of syphilis atherosclerotic disease of the coronary arteries and

the aorta would seem to be most likely from the symptoms and manifestations given. An electrocardiogram might be of value.

It would be logical to treat this patient on the basis of angina pectoris under such conditions. The program should be based on increased rest and limitation of activity below the level at which pain is experienced. Small feedings at more frequent intervals, and limitation of fluid intake are important. Vasodilator drugs may be of value. Glyceryl trinitrate or its equivalent may relieve the symptoms of pain and distress after they have appeared. In some cases theobromine, theophylline or their salts may be useful in limiting the frequency and severity of the attacks. Even if syphilis is found to be responsible for aortic disease, such therapeutic measures often result in some relief until appropriate treatment has become effective.

BITTERLING TEST FOR ESTROGENIC SUBSTANCE

To the Editor—Has there been any recent work on the so-called pregnancy test in which the Japanese bitterling is used? I have the report of Kanter, Bauer and Klawans published in the Dec. 29, 1934 issue of *THE JOURNAL*. Here in our diagnostic laboratory we have been conducting the Friedman modification of the Aschheim-Zondek test for several physicians in this vicinity. The results on a whole have been satisfactory but every year about this time our supply of rabbits becomes depleted. If the test using fish is dependable we should like to obtain some. Is there any place closer than the Breeding & Laboratory Institute, 567 Third Avenue, New York, where these may be obtained?

E. F. WALLER, Instructor, Veterinary Pathology, Ames, Iowa.

ANSWER—The test on the bitterling has not been advocated as a test for pregnancy to replace the Friedman test. So far the work has indicated that this is a test for estrogenic substance, although it may indicate androgen. The Friedman test makes use of the anterior pituitary gonadotropic hormone, a factor the excess of which appears in the urine very early in the course of pregnancy, excess of estrogenic substance not ordinarily becoming apparent until the gestation has progressed further. It is not deemed advisable for the ordinary laboratory to substitute the bitterling test for the other biologic tests now in general use. In cases in which a question of diagnosis of ectopic pregnancy, missed abortion or placental polyp has existed the bitterling test has been found valuable because of the apparent existence of excess of estrogenic substance when the excess of gonadotropic substance has been dissipated.

EFFECTS OF FACIAL MASSAGE

To the Editor—I have been asked by two women patients of mine whether facial massages can be given too frequently. Various opinions have been had from different beauty parlors here, some beauty workers maintaining that they should not be taken more than once in two weeks and others once a week; others say that they cause sagging of the facial muscles. I have said that they cannot be taken too often and are stimulating. I have suggested that if one must take them once a week is not too often and is stimulating and that one has no fear of causing sagging and the resultant wrinkles from such massage. What is your opinion on this? Please omit name and address.

M. D. Ohio

ANSWER—So far as known, the most important effect of massage on muscle is to increase the circulation and thereby its nutrition. Chemically it is observed that massage will aid in preserving the tone of muscles. There is no reason to believe that this should not also apply to the facial muscles.

Scientific massage is an effective treatment in cases of facial paralysis to prevent the sagging of facial muscles. Daily treatment is usually given to these patients with benefit.

It would seem that correctly applied massage could also be given to normal muscles at the same frequency with no harmful effects. The additional cosmetic treatment of beauty parlors is another consideration.

ETIOLOGY OF HERPES

To the Editor—In *THE JOURNAL*, February 15, page 564, I find a statement that the lesions of herpes are due to efferent nerve impulses liberating a histamine-like substance in the skin. Would you if possible kindly supply me with the authority for this statement?

TRYGVE GUNDERSEN, M.D., Boston

ANSWER—Sir Thomas Lewis and H. M. Marvin (*Heart* 14:27 [April] 1927) brought forward experimental proof that the action of the so-called antidromic impulses of Bayliss originating from lesions of the posterior root ganglion is to produce vasodilatation of the arterioles and capillaries which in turn is due to the local liberation of the H substance, a chemical body the action of which on these minute vessels is the same as that of acetylcholine and histamine. He included the formation of herpetic vesicles and trophic changes in the skin among the effects of the peripheral release of the H substance. More

recently some evidence has accumulated that there are vasodilator efferent pathways in the posterior root. The literature has been summarized by Kahr and Sheehan (*Bram* 56:265 [Sept.] 1933). According to some of these studies the vasodilator impulse producing herpetic vesicles does not travel in the ordinary sensory pathways, as thought by Bayliss, but is carried in the efferent vasodilators of the posterior root.

DIAGNOSIS OF PREGNANCY AFTER ABORTION

To the Editor—A patient who in the past has had regular menses with periods twenty-one days apart was due to menstruate January 25 and having gone four days past this date consulted an abortionist who as near as she knows, sounded the uterus and gave her quinine. Two days later menstruation began and continued for three days. Not being cognizant of the history I had an Aschheim-Zondek test done which was positive. Would the hormone content of the urine remain high enough throughout the month that has ensued to cause ovulation in the rabbit or is the positive test indicative of the fact that either the pregnancy was not terminated or the patient has again become pregnant? She has not menstruated since the period following her manipulation and according to her old cycle was two days overdue at the time the test was done. Please omit name.

M. D. Kansas

ANSWER—The positive Aschheim-Zondek test speaks for a pregnancy, either a new one or the old one going on uninterrupted. In most cases the test is negative by the tenth day post partum or post abortion. The possibility of an ectopic pregnancy or of a missed abortion must be considered. If the size of the uterus is consistent with the period of amenorrhea it is most likely a uterine pregnancy which was unaffected by the instrumentation. If the uterus is smaller and a mass is present on either side, an ectopic pregnancy is the most likely probability. This diagnosis would be strengthened if the amount of blood lost following the attempt at abortion was less than the amount passed during a normal period. Again, if the uterus is smaller than one would expect to find after the missed periods, a missed abortion is one of the greatest possibilities.

APICAL ABSCESSSES OF TEETH

To the Editor—In *THE JOURNAL*, January 4, in *Queries and Minor Notes* you state that the clinical and laboratory history in thousands of such cases have shown that such conditions can be cured and the patient remain perfectly well in more than 70 per cent of the cases. This statement referring to apical abscesses of the teeth. While I agree with the general thought expressed I should like to know on what authority this statement is made.

LOUIS I. GROSSMAN, D.D.S., Philadelphia

ANSWER—The statement quoted by the correspondent was of course more or less general. It was based on the records of the department of pathology and therapeutics in the treatment of pulpless teeth in the clinic of the College of Dentistry of the University of Illinois. The department has clinical records of 7,922 cases. Of this number 1,953 have been studied which means that they have been followed for from one to sixteen years after the completion of treatment. At the last tabulation of the 1,953 cases studied, 76 per cent had remained negative throughout the period of observation and this is without any selection whatever, even with regard to the original condition of the tooth when treatment was started, or the personnel of the students carrying out the treatment. A new tabulation of cases is now in progress and will be furnished to inquirers when completed.

TREATMENT OF FRACTURES IN ELDERLY PATIENTS

To the Editor—A man aged 84 is suffering from a fracture of the hip. He is in poor physical condition having had strokes previously. I have him in a new extension splint of DePuy with a cast on each leg and a splint attached to each leg with a set screw for extension and pressure on the well leg. A young man with a spiral fracture of the lower part of the tibia is unable to hold it in good apposition although it is straight. I have him in a cast. What treatment do you advise in each of these? Please do not publish name.

M. D. Oklahoma

ANSWER—The patient of 84, with the fracture of the hip is not likely to obtain a bony union by the use of the DePuy splint, if the fracture is through the neck of the femur. If it is a fracture at the base of the neck or through the intertrochanteric region the result may be good. Fractures through the small part of the neck in old persons are best treated by the Whitman abduction and inward rotation, with a long plaster-of-paris spica cast for at least four months. If the patient is a good surgical risk much time can be saved by performing a Whitman reconstruction operation, removing the head of the femur and transplanting the trochanter major downward on the shaft. The Brackett operation might be considered but the possibility of necrosis of the head at the age of 84 must be admitted.

Spiral fractures of the lower part of the tibia may be treated conservatively by traction in a Thomas splint, a Sinclair skate being glued to the sole of the foot and further fastened by short strips glued to the dorsum of the foot. The general tendency of the times is to make the traction by Kirschner wires through the upper and lower ends of the tibia, enclosing the wires later in a plaster-of-paris cast. Good results have been attained also by open operation, with use of the Parham-Martin band. The latter method is not free from the danger of infection and possible failure of union.

ABSORPTION OF CITRATES

To the Editor—Please tell me something of the metabolism of citrate (of sodium and potassium). 1 When given by mouth is it absorbed as citrate? Is it oxidized at once in the liver to bicarbonate or does it reach the general circulation as citrate? If so for how long does it persist as citrate in the blood? 2 When given intravenously, in doses of say, 2 to 5 Gm. (from 100 to 250 cc. of 2 per cent solution) how long does it persist as citrate in the general circulation? Where is it oxidized to bicarbonate? 3 Some years ago it was asserted and denied that bitartrate was oxidized to bicarbonate giving alkaline urine will you please tell me whether there was any authoritative conclusion? Please omit name.

M D, New York.

ANSWER.—Citric acid occurs regularly in the blood and urine of man and of many animals. It is also found in milk. The daily elimination in the urine amounts to about 0.1 to 0.5 Gm.

1 It is absorbed as such when given by mouth but is rapidly destroyed, so that only about 0.2 per cent of the ingested quantity is found in the blood. After ingestion of 20 Gm of citric acid only 2 Gm is eliminated as such, the maximum of elimination is reached in about two hours. There is experimental evidence suggestive that the liver and, to a much less extent, the kidney are capable of oxidizing citric acid.

2 When given intravenously therefore it will not persist in the circulation very long and it will be oxidized in the liver.

3 Tartaric acid differs greatly from citric acid in that the former is destroyed by the intestinal bacteria probably to the extent of about 80 per cent. The remaining 20 per cent appears in the urine unchanged. Recent investigations have shown that tartaric acid is not oxidized in the system and that after intramuscular injection practically all of it can be recovered in the urine within ten hours.

IRREGULAR MENSTRUATION AND SAFE PERIOD

To the Editor—Apropos of the query on sterility (*THE JOURNAL*, February 22 p 646) I have a patient who can definitely place her last two pregnancies on coitus within forty-eight hours of her menstrual period—both occurring before menstruation. Her periods are very irregular. Would this fact influence the safe period? Kindly omit name.

M D North Dakota

ANSWER.—A woman whose periods are very irregular, i. e., whose written record of her menstrual cycles for a period of eight months or more shows a variation of more than ten days between the shortest cycle and the longest cycle, cannot, for practical purposes, determine her safe period. If the patient in question falls within this class, it is obvious that she cannot say with confidence that coitus which resulted in conception occurred within forty-eight hours before her expected menstruation because the fact that menstruation did not recur, coupled with an admitted great irregularity, makes it impossible to determine what the length of the current cycle would be and consequently impossible to state with confidence that the coitus in question occurred within forty-eight hours of menstruation. (If this case does not fall within this class, it would be necessary to furnish further data on the case, as outlined in the rules to be followed in the use of the safe period, contained in the article "Natural Conception Control," published in *THE JOURNAL*, Oct. 19, 1935, in order to point out the causes for any disappointment.)

LIQUID PETROLATUM AND VITAMIN A ABSORPTION

To the Editor—I have recently heard the statement that mineral oil used as a laxative absorbs many of the vitamins from the system and therefore is not a proper product to use. Is this fact or fancy? Please omit name.

M D New York

ANSWER.—There are experimental observations on record which show that the ingestion of a very large proportion of liquid petrolatum in the food of animals does interfere with fat-soluble vitamin absorption especially if the animal is on a vitamin low diet. There is no proof however available that the ordinary therapeutic use of liquid petrolatum taken in conjunction with normal diet will induce a hypovitaminosis in the human being.

Book Notices

Family Behavior A Study of Human Relations By Bess V Cunningham Ph D Cloth Price \$2.75 Pp 471 with 7 illustrations Philadelphia & London W B Saunders Company 1936

Intended primarily as a textbook for the student of college age who is interested in the problems of adjustments of modern families to life in a complex community such as exists at present, the Cunningham volume should prove of value to the practicing physician or pediatrician for several reasons First, to be professionally effective, physicians must be thoroughly familiar not only with the problem of family adjustment as such but with the psychologist's approach to it Second, this book is written readably for the student and not highly popularized for the apparently unlimited capacity of the lay mind in this field Third, it recognizes that there is something in the picture besides sex Fourth, the author is thoroughly qualified in terms of background and experience to present sound and practical material on a conservative basis Fifth, there is an ample bibliography for further study, if desired Accordingly the book is recommended

The progress of the book is about as follows Why study family behavior? Definition of family and behavior How to study the family Neighbors and neighborhoods, with consideration of national and racial origins, variations in belief, socioeconomic status, intelligence, and educational and amusement facilities Working and sharing income Using leisure Adjusting to community life, including to neighbors and to newer influences The nurture of personalities Maintaining healthy minds Careers for parents Children and their parents Growing up Families of tomorrow In a sense the book represents an attempt to analyze the possibilities of mental hygiene in family and community life Matters physical are almost entirely omitted Accordingly the reader would obtain from it suggestions as to the philosophy of life and relationships which would be successful in the present social revolution, with, however, scrupulous omission of political philosophies For the student there are continually presented problems for further consideration This with the text and generous bibliographies assures an adequate textbook However, he who seeks methodology as such will be disappointed The book, almost in toto, is theory rather than "how to do it" Yet the book is so written that the reader should have no great difficulty in making practical application of the material presented

With family adjustments internal and external, one of the major social problems confronting the physician (who must heal or prevent social as well as physical and mental ills today), this book deserves a place in medical libraries built for professional improvement.

Précis de biologie animale à l'usage des candidats au certificat d'études physiques chimiques et biologiques et à la licence ès sciences Par M Aron professeur à la Faculté de médecine de Strasbourg et P Grassé professeur à la Faculté des sciences de Clermont Ferrand. Cloth Price 80 francs. Pp 1016 with 642 illustrations Paris Masson & Cie 1935

This textbook is intended primarily for the use of students who are candidates for the "P. C. B." certificate (physical, chemical, biological). The authors have attempted to orient the student in the field by presenting general biological principles rather than descriptive and systematic biology In pursuit of this plan they have given over the first 400 pages to discussion of such subjects as cell organization, division and general physiology sexuality, heredity regeneration, nutrition of organisms the relation of organisms to their environment, and

growth. The animal groups are presented briefly and concisely and the final chapters contain discussions of problems of speciation and evolution. The numerous illustrations increase the usefulness of the book. The type, while small, is clear and legible. The authors have produced an interesting and stimulating book which is more comprehensive than many textbooks in general biology. The emphasis placed on research and the importance of experimental method is especially commendable.

Memorandum Book of a Tenth Century Oculist for the Use of Modern Ophthalmologists. A Translation of the *Tadhkirat of Ali Ibn Isa of Baghdad* (cir 940 1010 A. D.) the Most Complete Practical and Original of All the Early Textbooks on the Eye and Its Diseases. The first edition in English by Casey A. Wood. Boards. Price \$8. Pp 232 with 21 illustrations. Chicago: Northwestern University 1936.

Tadhkirat al-kahhalin, or the Memoranda for Oculists, was written by Ali ibn Isa, a Nestorian Christian oculist practicing in Baghdad around the year 1000 A. D. Although not one of the earliest of the Arabian books on ophthalmology, it is probably the most complete of that era and one of the few in which acknowledgment is made to earlier Greek and Arabian ophthalmologists. In his well known history of ophthalmology, Hirschberg listed ten known copies of the work. Dr Wood was fortunate enough to obtain the eleventh copy, which is complete and modern, as well as the twelfth copy, which is older and somewhat fragmentary. With the assistance of Dr Max Meyerhof and others, Casey Wood has again produced an enduring piece of work in the translation of this early textbook. It is dedicated to his lifelong friend Dr Harold Gifford and forms a monument of which any man may well be proud. The book making was done by the Lakeside Press under the supervision of Northwestern University and particularly Dr Sanford Gifford and is a creditable piece of work.

Two hundred and twenty eight pages of translation of medieval medicine sounds like difficult reading, but to one interested in the subject it is fascinating. The ophthalmology of Ali ibn Isa was only what could be seen with the naked eye. He had no ophthalmoscope or slit lamp and as a result his major observations were confined to diseases of the surface of the eye. But he had a good classification of such diseases, even though his knowledge of the etiology was weak. However, to make up for that he was strong on therapeutics and he gave some thirty-one pages of description of medicinal agents and how they were prepared and used. The surgery was of course rudimentary and primitive, but it is interesting to hear him talk as glibly of anesthetics as we do today.

There is much food for thought in this book. In the first place, it fills a definite gap in our historical knowledge and it will stimulate a desire for further reading in the history of ophthalmology, particularly among the younger men. In the second place it is a translation written in the flowing easy style of a finished literateur and consequently is delightful reading. And in the third place, it is a piece of fine book making of which we may all well be proud. Casey Wood has again distinguished himself.

Les parasites érythrocytaires révévés par la splénectomie. *Bartonella et éperythrozoon.* Par le Docteur David Weinman. Travail du Laboratoire de Parasitologie de la Faculté de médecine de Paris. Paper. Pp 103. Paris: Amédée Legrand 1935.

This memoir gives a comprehensive review of the intracellular parasites of red blood cells which appear after splenectomy. The first and much the largest section comprises an extended and excellent literature review in three chapters dealing respectively with the genus *Bartonella*, *Bartonella muris*, and other bartonellas. As would be expected *Bartonella muris* is given much the most extensive treatment. It includes a complete review from the standpoint of history, epidemiology, course of infection, histopathology, symptomatology, immunology and morphology of the parasite. In the second section there are three chapters dealing with *Eperythrozoon coccoides* of the white mouse, other *eperythrozoa*, and certain doubtful forms. The third section deals with the author's original observations on *Eperythrozoon coccoides* and contains data on the morphology of the parasite, transmission and virulence. There is a full bibliography of eleven pages. Investigators interested in this group of organisms will find this a useful review of the subject.

The Life and Works of Charles Barrett Lockwood (1856 1914). By Eric C. O. Jewesbury. M.A. B.M. B.Ch. (The Wix Prize Essay). Bartholomew's Hospital 1934. Cloth. Price 3s. 6d. Pp 103 with 12 illustrations. London: H. K. Lewis & Co., Ltd. 1936.

This is a short biography of a surgeon who lived through the interesting transition period of surgery from antiseptic to asepsis and who was a pioneer of aseptic principles at St. Bartholomew's, the hospital in which he worked. A biography written more than twenty years after one's demise is likely to magnify the good qualities and accomplishments and minimize the faults and peculiarities of the individual concerning whom it is written. It does not appear so in this case. Based on personal interviews with many people who knew him, the author portrays the life and work of this man clearly and yet briefly, leaving out all the minute details. Lockwood is presented as a man of courage and determination, an indefatigable, thorough worker who accomplished much. He was an expert anatomist, a practical bacteriologist as well as an excellent and conscientious surgeon, a pioneer in spirit. As a teacher he was inspiring, forceful and entertaining in the informal demonstrations in the wards. Formal lectures he found most trying, yet no member of the staff attracted so large an audience. His rather numerous published lectures and essays, on the other hand, have been described as "some of the finest that have appeared in the world of medical literature." The record of the man, as portrayed by the author, is an inspiration and should be read by all young and aspiring surgeons.

Urological Nursing. By David M. Davis. M.D. Professor of Genito-Urinary Surgery, Jefferson Medical College. Second edition. Cloth. Price \$2.25. Pp 195 with 87 illustrations. Philadelphia & London: W. B. Saunders Company 1936.

This small volume should prove valuable to nurses in charge of urologic cases, and an absolute necessity to nurses in charge of urologic wards or operating rooms. The chapters concerned with the anatomic and clinical aspects are sufficiently complete to serve as a good background for efficient nursing, but Dr. Davis has successfully checked any tendency he might have had to enlarge on these subjects from the strictly medical point of view. The illustrations are to be commended, particularly those depicting various types of apparatus used in carrying out drainage of the bladder, both through the natural channel and through suprapubic and perineal incisions. The urologic armamentarium, always a most complicated one, has become even more so with the great popularity of transurethral operative procedures, and Dr. Davis deserves great credit for discrimination in selecting instruments for illustration and detailed description. The question of sterilization of instruments is discussed adequately.

L'action des rayons ultra violets et des rayons X sur les nerfs périphériques. Par Jacques Audiat, docteur ès sciences. Préface de Pr. A. Strohl. Paper. Price 25 francs. Pp 88 with 23 illustrations. Paris: Masson & Cie 1935.

For many years nerve tissue in general has been held to be comparatively resistant to roentgen and ultraviolet rays. The careful experiments of the author, by electrophysiologic methods on isolated nerves, indicate that, under certain conditions of technic (doses of rays), the function of peripheral nerves may be influenced by irradiation. The experiments appear to have been carried out with care and skill, and the manner in which the author attempts to interpret his results shows a high degree of scientific reserve. In connection with roentgen rays, unfortunately, the technical details given are not sufficiently clear. Audiat seems to regard rays generated at 110 kilovolts as penetrating. Medical radiologists would probably find it difficult to accept this view except from the limited point of view of the experimental physiologist. Moreover, doses of the order of 300,000 roentgens might be expected to influence a nerve or any other kind of living tissue; the therapeutic doses used in medicine are so much smaller that the experimental results obtained by the author can hardly be translated into medical terms. It would be interesting to know how 300,000 roentgens could be obtained in ten minutes with the voltage and filtration given. Nevertheless, physiologists interested in physiology will find this title interesting.

Prof Dr G Grijns' Researches on Vitamins 1800 1911 and His Thesis on the Physiology of the N. opticus, Translated and Reedited by a Committee of Honour on Occasion of His 70th Birthday Paper Pp 254 Gorinchem J Noorduyt en Zoon N V 1935

This is a memorial volume commemorating the seventieth birthday and academic retirement of Dr Gerrit Grijns. The book contains his comprehensive and classic treatise on polyneuritis gallinarum with his original protocols translated into English and his first scientific paper, 'The Physiology of the Optic Nerve,' translated into German. The latter paper is unusual in that while it was published before finishing his studies at the University of Utrecht the data remain valid to this day. At the end of the book is a bibliography of the ninety three publications of Professor Grijns. As one of the fundamental investigators in the field of vitamins and as a scholar and physician, Dr Grijns is deserving of the homage and appreciation of his scientific colleagues all over the world.

Theoretische und experimentelle Studien zur Methylenblaufärbung des Nervengewebes. Von Prof Dr Arnold Schabadach. Heft 1 Acta morphologica. Arbeiten aus dem morphologischen Laboratorium der Filiale des Institutes für experimentelle Medizin (Wien) und dem Staatlichen Anatomischen Institut in Gorkij (UdSSR). Vorstand Prof Dr Arnold Schabadach. Cloth Pp 244 with 24 illustrations. Gorky State Publishing House 1935.

This first volume of the Acta Morphologica presents a survey of the work of the last fifty years on the staining of the nervous system with methylene blue. It includes not only an account of the technic but also a consideration of the chemical factors involved. Excellent photomicrographs show the structure of the sympathetic plexuses in the walls of the viscera.

Bibliography in Health Education for Schools and Colleges. Selected and Annotated by Mary Ella Chayer R N A M Instructor in Nursing Education Teachers College Columbia University. Cloth Price \$1.50. Pp 100. New York G P Putnam's Sons 1936.

Today the practicing physician is being called on more and more to furnish information on health and hygiene. It is difficult if not impossible for him to keep himself informed on all the phases of the subject, to read and know the best books and the latest and most authoritative pamphlets as well as periodicals. The author presents in this volume a guide for the physician that is decidedly worth while. The manner of classifying the material is well done and labor saving to the reader. At a glance he can choose his subject and then determine easily whether he wants a book, a pamphlet or an article from a periodical, since all the subjects are divided in this manner. As with all bibliographies on health, frequent revision will be needed.

Handbook of Surgery. By Eric C Mekie M.D. Ch.B. F.R.C.S. Medical Officer, Malayan Medical Service. With a foreword by John Fraser M.C. M.D. Ch.M. Regius Professor of Clinical Surgery University of Edinburgh. Fabrikoid. Price \$4.50. Pp 699 with 24 illustrations. Baltimore: William Wood & Company 1936.

The author of this little volume says in his preface "It has been my aim to set down only what are the salient features of the subject which must be known ere the student presents himself for examination." The surgeon actively engaged in practice tends to forget the beginner's point of view and what a tremendous volume of information he is expected to acquire and master in a few short years. Volumes such as this concisely and clearly written, though necessarily dogmatic, are helpful guides to what is important and essential. To indicate this clearly and in an interesting and logical fashion is a praiseworthy achievement, and the author has accomplished it admirably.

Detachment of the Retina. Operative Technique in Treatment. By J Cole Marshall M.D. F.R.C.S. Senior Surgeon Western Ophthalmic Hospital London. Cloth Price \$2.75. Pp 80 with 44 illustrations. New York & London Oxford University Press 1936.

This is a brief outline of most of the operative methods for detachment of the retina. The author observed most of the various methods that are described practiced by those who devised them. The others are briefly reviewed from the original articles. The book is a fair rehash of all that has preceded in this field. No new ideas are advanced, no original procedures are described and the author's personal opinions are conspicuous by their absence. The descriptions are sometimes difficult to follow and the arrangement of the text could be improved. The book contains little to recommend it.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts. Sequelae of Herniotomy Compensable.—The claimant developed a right inguinal hernia as a result of lifting a heavy keg of nails in the course of his employment, and submitted to an operation. For a number of years prior to the operation he had a chronic inflammation of the spine and hypertrophic spondylitis that being a growth of bone and cartilage from the spine causing pain. The long confinement in bed incident to the herniotomy aggravated these conditions and also caused spastic colitis. As a result of these sequelae, he was unable to do any manual work. The industrial accident board awarded him compensation in accordance with a special provision of the Texas workmen's compensation act pertaining to hernia, which authorizes, in the event of a successful operation, compensation for a limited period in addition to expenses for necessary medical and surgical care. The claimant then sued his employer's insurer the Zurich General Accident and Liability Insurance Company, in the United States district court for the eastern district of Texas, to set aside the board's award and to recover instead compensation for total permanent disability under the general provisions of the act. From a judgment in favor of the claimant, the insurer appealed to the United States circuit court of appeals, fifth circuit.

The Texas workmen's compensation act, said the circuit court of appeals authorizes compensation for certain specific injuries, including hernia, and also for injuries in general resulting in partial or total incapacity for work. An employee who suffers a specific injury is not confined to the compensation allowed for that specific injury if that injury, or the proper or necessary treatment therefor, causes other injuries which render him unable to work. The court was of the opinion that the aggravation of his preexisting ailments and his consequent total incapacity for work were traceable to his injury, received in the course of his employment, and to the treatment called for by that injury. The court held therefore that the claimant was entitled not only to compensation for the hernia directly caused by the accident but also for the total and permanent disability resulting from the aggravation of his preexisting ailments, which prior to the operation had no disabling effects. The judgment of the trial court was therefore affirmed.—*Zurich General Accident & Liability Ins Co v Daffern, 81 F (2d) 179*

Charitable Hospitals. Charitable Status Need Not Be Negatived in Complaint Alleging Injury.—An appendectomy was performed at the defendant hospital on the plaintiff's six year old boy, a pay patient. Some time subsequent to the operation, the attending physician ordered the injection of one-fourth grain of codeine. A nurse employee of the hospital injected instead one-fourth grain of morphine. The patient died soon thereafter from the effects of the injection. The plaintiff then brought suit against the hospital. The defendant hospital demurred to the complaint and, when the trial court sustained that demurrer, the plaintiff appealed to the Supreme Court of Utah.

In support of the ruling of the trial court on the demurrer, the hospital contended that as a charitable institution it was not liable for the negligence of its nurses, and that it was incumbent on the plaintiff, in his complaint to plead that the hospital was not a charitable or eleemosynary institution. With this contention, the Supreme Court disagreed. For a complaint to be good against a general demurrer, the court said, the plaintiff is not required to plead so far as corporate existence is concerned, the nature or purposes of the corporate defendant. Furthermore when one is charged with responsibility for wrongful or tortious behavior and exemption therefor is claimed it is essentially defensive matter. The Supreme Court after reviewing at some length the differing rules in the various jurisdictions relating to the liability of charitable institutions for injuries occasioned by the negligence of their servants,

and after discussing the factors that may enter into a determination of the charitable status of a hospital, held that the trial court should have overruled the demurrer to the complaint and permitted the defendant hospital to introduce evidence, if it so desired, to establish the charitable status of the hospital. The judgment of the trial court was therefore reversed and the cause remanded, with directions to overrule the defendant's demurrer, and permit the parties to proceed further.—*Sessions v. Thomas Dec Memorial Hospital Assn (Utah) 51 P (2d) 229*

Alcoholism "Intoxication" defined—Whether or not a person is intoxicated, said the Supreme Court of Illinois, is a question of fact for the jury, but what constitutes intoxication is a question of law to be defined by the court. We have held, continued the court, that the terms "drunk" and "intoxicated" are synonymous (*People v Rowland*, 335 Ill 432, 167 N E 10). The term "intoxication" is of such elasticity as to require legal definition when applied to a criminal statute. The courts of different states have applied varying definitions to the term. In Kansas it has been held that a person is intoxicated within the meaning of an accident policy if his faculties are affected to such an extent as to impair his ability to care for himself (*Richardson v Business Men's Protective Association* 129 Kan 700, 284 P 599). In Oregon it has been defined as drunkenness evidenced by abnormal excitations of passions or feelings and impairment of mental and physical faculties (*Brady v Schmitzer*, 135 Ore. 250 295 P 961). In Louisiana it is held to mean the condition of being under the influence of intoxicating liquor to such an extent as to have lost normal control of the faculties (*Valeri v Mutual Life Ins Co of New York*, 151 La 405, 91 So 818). All the definitions, observed the court, differ in wording but each of them includes the central idea of an impairment of the faculties of care and caution. The trial court in the present case, said the Supreme Court, erred in refusing to instruct the jury, as requested by the accused that such intoxication as would make the driving of a car unlawful was that degree of intoxication which would render the driver incapable of giving that attention and care to driving that a man of prudent and reasonable intelligence would give. For this and other errors committed by the trial court, the judgment of conviction of manslaughter was reversed and the case remanded.—*People v Schneider (Ill)*, 200 N E 321

Life Insurance Death from Pneumonia Following Heat Prostration a "Death by Accidental Means"—The defendant insurance company issued a policy of insurance on the life of one Thomas O'Connell which provided for the payment of double indemnity on proof "that the death of the insured resulted directly and independently of all other causes from bodily injury effected solely through external violent and accidental cause." The insured, a plumber, after working in a ditch for some hours laying sewer pipe, collapsed from the heat and fell, striking his head at the base of the skull. Within twenty-four hours he developed pneumonia, from which he died. The beneficiary sued on the policy to recover double indemnity. The defendant contended that it was not liable for double indemnity because the insured's death was not caused by accidental means. The jury returned a verdict for the defendant. The trial court, however, gave judgment in favor of the plaintiff notwithstanding the verdict. The defendant thereupon appealed to the Supreme Court of Wisconsin.

It was conceded that the blow on the head neither caused nor materially contributed to the insured's death and that the pneumonia was induced by heat prostration. The sole question, the Supreme Court said, was whether heat prostration satisfies the policy requirement that death or bodily injury be "effected solely through external violent and accidental cause." There is no legal distinction, said the court, between sunstroke and heat prostration however different their medical effects may be. Injuries resulting from heat prostration or sunstroke are not only accidentally effected but produced by accidental means. The insured's death was therefore, held to have been "effected solely through external, violent and accidental cause."

The judgment in favor of the beneficiary was affirmed.—*O'Connell v New York Life Ins Co (Wis) 264 N W 253*

AMERICAN ASSOCIATION FOR THE STUDY AND CONTROL OF RHEUMATIC DISEASES

Third Annual Meeting and Fifth Conference on Rheumatic Disturbances
held in Kansas City, Mo. May 11 1936

LORING S. SWAIN, M.D., Secretary

The Clinical Approach to the Rheumatic Patient

DR. RUSSELL L. HADEN, Cleveland When confronted with a "rheumatic" patient, the clinician should have a definite plan of approach. The just differentiation is between articular and nonarticular skeletal disease. If the patient has a true arthritis there must be some clinical classification such as the following:

1 Arthritis due to a known cause, such as traumatism, a specific infection, a metabolic disturbance, a constitutional abnormality, some neuropathic disorder or serum disease.

2 Arthritis due to an unknown cause, including rheumatic fever, rheumatoid arthritis and osteo-arthritis.

The management of arthritis due to a known cause is usually clearly indicated. Since by definition the causes of the second group are unknown, these should be thought of in terms of unknown specific etiologic factors, most probably an infection in rheumatoid arthritis and an aging or disturbance in nutrition of the cartilage in osteo-arthritis and of influencing factors which may often be found and treated. The influencing factors in rheumatoid arthritis may be designated precipitating factors such as exposure, exhaustion, specific infections, focal infections, undernutrition, anemia, toxemia or diminished blood flow. The influencing factors in osteo-arthritis may be designated accelerating factors. These are abnormal metabolism, trauma, disturbed circulation, toxemia, nutritional deficiency, gastro intestinal disturbances and exhaustion. To uncover the precipitating and accelerating factors, a careful clinical and laboratory survey is necessary in each patient. Treatment should be planned for a patient individually on the basis of the conditions found in such a survey.

Differential Diagnosis of Arthritis from Standpoint of Pathology

DR. EDWIN P. JORDAN, Chicago Gout has long been presumed a disorder of metabolism. Although the alleged factors are not understood those believed to play a part are hereditary predisposition, lead and alcohol. The newer chemical methods have demonstrated an increase in uric acid content of the blood. The significance of this change is uncertain as some normal individuals show a uric acid in excess in gout as in cases of uremia and leukemia. The second major tissue change in gout is the deposit of the urates with an elective affinity for fibrous tissues around joints and in the lobes of the ear, and in the

Rheumatoid and atrophic arthritis are the same. Osteoarthritis is a hypertrophic arthritis are the same

later stages in the bone around joints. If this precipitation is slow there are few secondary changes but if rapid there are marked inflammatory redness and swelling and pain. Little is known of the microscopic picture at this stage, or of the inflammatory exudate in the joint during the acute attack.

Gonococcal infection may produce definitely an arthritis. There may be two or more types, but certainly one type invades the joint. In one stage it involves the synovial membrane, producing inflammatory reaction with infiltration with leukocytes, lymphocytes and macrophages. An inflammatory exudate follows from which gonococci can be isolated. A second type, a true sensitization of the joint to products of metabolism of the organism, is believed to occur in which the organism cannot be isolated and little is known of the pathology. Probably the finding of large numbers of eosinophil cells either in the joint fluid or in the synovial membrane would help to corroborate the conception of the existence of the disorder as a pathologic entity.

In degenerative arthritis no consistent lesions have been described outside the joints other than degenerative changes, but the end results of this arthritis are characteristic. Nichols and Richardson say "The joint cartilage is irregular in thickness, and markedly so in structure. It is fibrillated and calcified. Its cells are swollen. Parts of the cartilage may be ossified. The underlying bone is thickened and dense. The marrow is fatty and fibrous. The synovial membrane is thickened, fibrous, and is thrown into villi. Several observers have noted cyst formation in the bone in the region of the joint." The primary lesion is in the articular cartilage which cannot repair, erosion and fragmentation of the cartilage follow, subchondral bone becomes dense and proliferates. Loose bodies occur. Most of the changes can be ascribed to the increasing trauma to the joint. A vicious cycle results.

In rheumatoid arthritis, constant deviations of the sedimentation rate suggest blood changes. The primary tissue affected is the synovial membrane. Diffuse proliferation of the membrane occurs, with increase in plasma cells, lymphocytes and eosinophils. Depending on the speed of the progress, lymphocytes and plasma cells increase. Polymorphonuclear leukocytes may appear either in the synovial tissue or in the lumen of the blood vessels. Perivascular infiltration may occur. There is constant increase in the fibroblasts. The pathologic changes suggest but do not prove the specific nature of rheumatoid arthritis. The experiments in rabbits by nonspecific allergic inflammation produce a picture similar to that in man. Key has produced the same picture by weak acids and alkalis and Jordan by acetone and turpentine. On the whole, it seems that the major forms of arthritis can usually be clearly differentiated on the basis of the characteristic pathologic picture which they produce.

DISCUSSION

DR. M. HENRY DAWSON, New York. The pathology of gonococcal arthritis is reasonably well known. The pathologic changes in rheumatoid and osteo-arthritis are not quite so clear. However, many detailed and excellent investigations have been made on the pathology of these two forms of arthritis. One of the best descriptions was that of Hoffa and Wollenberg in 1908. A year later Nichols and Richardson published their classic monograph. In 1926 Heine published his monumental study on the relationship between age period changes and degenerative arthritis. Among other contributions have been the studies of Allison and Ghormley, Timbrell Fisher and Klinge and his associates. The one inescapable conclusion from all these studies is that rheumatoid arthritis and osteo-arthritis represent two totally different pathologic processes. Rheumatoid arthritis is an inflammatory process related in some very intimate way with infection. Osteo-arthritis is an age period, degenerative disease not associated with infection in any direct manner. Pathologically the distinction between rheumatoid arthritis and osteo arthritis is quite as sharp and well defined as that which exists between syphilitic aortitis and arteriosclerosis. Knaggs expressed a contrary opinion. Originally Knaggs believed that the two diseases under discussion were distinct entities but after studying the Strangeways collection of joints he arrived at a different conclusion. I believe that this contrary point of view can be explained by the fact that the material studied consisted largely of old and 'burned-out' specimens of the two diseases. Secondary degenerative

changes are frequently superimposed on rheumatoid arthritis, also degenerative arthritis is an extremely common event, especially in the later decades of life. It is not surprising that in certain cases the changes of the two diseases should coexist in the same patient and even in the same joint. Concerning the pathology of rheumatoid arthritis, the subcutaneous nodule, to my mind, constitutes the most characteristic lesion. It is frequently possible to make a positive diagnosis from the histologic appearance of the nodule alone. It is true that only 15 to 20 per cent of patients with rheumatoid arthritis show these nodules, but when found they are pathognomonic. They are never seen in osteo arthritis.

DR. PHILIP S. HENCH, Rochester, Minn. Since there is no one clinical or laboratory feature pathognomonic of atrophic arthritis, it would be helpful in diagnosis if there were at least a specific pathologic lesion. Allison and Ghormley believed that the nodular collections of round cells which they described, seen in synovia and epiphyseal bone, are specific for atrophic arthritis. Somewhat similar collections were described by Timbrell Fisher, who recently spoke of them, however, as being "perivascular." Allison and Ghormley did not consider them perivascular. May I ask Dr. Jordan how he would describe them? I cannot agree with Dr. Dawson that subcutaneous fibrous nodules are seen only in atrophic arthritis. Dr. Slocumb and I have seen numerous subcutaneous nodules in many cases of fibrositis in which even after years of the disease arthritis has never developed.

DR. J. ALBERT KEY, St. Louis. The synovial lining cells are connective tissue cells. Twenty-four hours after the joint is irritated these cells are changed and an osteo-arthritis joint is often irritated. As regards a clear-cut distinction between osteo-arthritis and rheumatoid arthritis, the more one studies the synovial membrane of osteo-arthritis the less will one believe that such a distinction exists. It has been the custom since osteo-arthritis was first found to begin in the cartilage—and that was a long time ago—to concentrate on the cartilage and bone, and almost nothing has been done on the changes in the synovial membrane of osteo-arthritis. The orthopedic men have recognized a villous arthritis. The men interested in arthritis have said that such a condition does not exist.

In following cases of osteo-arthritis I am impressed with the fact that an individual may have marked degenerative changes in the joint for many years and have no clinical symptoms. Then something may happen and the joint gets hot, is filled with exudate and becomes an acute joint. That joint is bound to have inflammatory changes in the synovial membrane. According to Dr. Dawson, that is a burned out rheumatoid arthritis which has developed compensatory changes as a result of degeneration of the cartilage. On the other hand, I am perfectly sure that it is chronic inflammation in an osteo-arthritis joint. And I have seen numerous specimens on which I have operated in which there were marked inflammatory changes in the synovial membrane. I do not know the origin of rheumatic nodules but I have never seen the pathologic picture such as Dr. Dawson described in rheumatoid arthritis presented by any other condition. I have excised these nodules and I was unable to explain how they came about. I have felt that the nodules of small round cells described by Ghormley and Allison are by no means constant in the synovial membrane of rheumatoid arthritis. It is only in old cases that they may be found and it is my experience that they are not perivascular.

DR. EDWIN P. JORDAN, Chicago. I do not know whether the aggregations of cells are perivascular or not, but I think that most of them are not. I have been able to find blood vessels going through them in only a relatively small percentage of the total number. With regard to the pathologic differentiation between degenerative arthritis and rheumatoid arthritis every one who has any opinion on that subject at all feels very strongly about it. There seems to be no middle point of view. Actually I think that the end result of the two processes in their pure form if there is a pure form and there seems to be, is decidedly distinct pathologically. On the other hand, I do not see as sharp a distinction between the processes when applied clinically. In other words in many instances the two seem to be intertwined in the one patient to such an extent that it is difficult to draw any hard and fast line between them.

The amount of synovial membrane involvement in what is supposed to be degenerative arthritis is sometimes almost as much as in rheumatoid arthritis. The inflammatory reaction may be fairly acute. It may be due in this instance to trauma from the bone rather than from infection. It may not be infection in rheumatoid arthritis, and hence it is exceedingly difficult to say in all instances during life, at least pathologically, that the process is one or the other. In some instances it is possible to differentiate with some certainty.

The British Activities for the Control of Rheumatism

LORD HORDER, London. I was under the impression before I came over that among the activities at Kansas City there would be a group meeting to discuss the control of rheumatism in the largest sense of that word. I find myself with some alarm and trepidation faced with a program that makes it appear to me that you are engaged in the study of rheumatic diseases from the clinical and pathologic side. I got a little comfort from hearing Dr. Boots say that some of the etiologic factors in rheumatoid arthritis are not yet certain but he took that comfort away from me by saying that we all know about osteo-arthritis. My critical faculty came to my aid, things might happen in the calf that do not happen in the human being. I am chairman of the National Society for the Control of Arthritis in Great Britain. We have in Great Britain a great deal of rheumatism of a disabling type. We have a great deal of disabling rheumatism to which we cannot as yet give any names. It has been definitely established through the ministry of health that there are more working hours wasted in Great Britain through conditions that are labeled chronic rheumatism, fibrositis, arthritis of indefinite origin, and so on, than in any other disease. So that nine years ago there was an effort to form a committee which would consist of doctors, industrialists, men of intelligence and foresight and the minister of health. That committee was aborted because it began at a time when we were faced with domestic economic problems of such dimension that we could not see our way to get the funds to run this committee. We have done up to the present very little work. We have succeeded up to the date of my leaving London in collecting about one third of the quarter million dollars that we aimed at getting to give this thing a proper trial. Our central committee at present is entirely medical. We hold that if one really wants an organization of this type to succeed to do good work and to keep straight it must be essentially medical. I notice that we have as you have all sorts of groups which are not controlled by medical men and women. They are both free countries and if a few people get together and want to do something there is nothing in our law to prevent them from doing it. We really have got an extremely good organization with the triad that I spoke of, medicine, the government in the person of the minister of health and the industrial magnates. What we propose is that as soon as we are not likely to be aborted a second time, because we have not yet gone publicly for appeals, our committee will become an advisory scientific committee to organizations. We hold that it is better to get a decently large fund and then to go to the public for smaller donations. We then can incorporate as a national campaign against rheumatism. Our activities will be first a study of the various aspects of the rheumatic problem including what we still call rheumatic fever. We shall have a research committee because we shall have money with which to subsidize research, just as our cancer campaign subsidizes both full and part time men, with researches of six months, twelve months and up to five years. With regard to treatment, we are still affiliated with the Red Cross rheumatism clinic, which is doing very good work in London and has two branches in the province. Here all the physical therapeutic measures which are so important in these chronic cases are available for the use of any patient sent in by members of the advisory committee or any one who is entrusted to him by a medical man. We expect naturally to increase the number of these rheumatism clinics and we also have a scheme for studying more intensively some of the cases of the rheumatoid group particularly. So we shall have a service for special research work and outpatient clinics for the more routine therapy. We have spas, so-called sanatoriums and watering places for the treatment of chronic rheumatic conditions. We have them repre-

sented on our medical committee and they sent us fourteen representatives. That is roughly what we are doing. We have apparently preceded us by about three years.

Differential Diagnosis of Rheumatoid (Atrophic) and Osteo-Arthritis (Hypertrophic, Degenerative)

DR. RALPH H. BOOTS, New York. These two groups account for about two thirds of all arthritis patients and there is a great difference in their prognosis and treatment. Rheumatoid arthritis is a multiple arthritis which seems to be part of a response to a generalized infectious process. Osteo-

Rheumatoid Arthritis and Osteo Arthritis

| | Rheumatoid Arthritis Atrophic arthritis Proliferative arthritis Chronic infectious arthritis | Osteo Arthritis Hypertrophic arthritis Degenerative arthritis Menopausal arthritis Senile arthritis |
|---|--|--|
| <i>Clinical Differentiation</i> | | |
| Geographic distribution | Most common in temperate climates; rare in the tropics | Climate not much of a factor |
| Family history | Usually a history of rheumatic fever or rheumatoid arthritis in an immediate member of family | Frequently a history of a similar form of arthritis in one or both parents |
| Past history | Occasionally a history of rheumatic fever, frequently of tonsillitis or sinusitis | Not characteristic; sometimes a history of trauma or faulty body mechanics |
| Age at onset | Any age; over 80 per cent between 20 and 50 | Rare before 40; in women most common at menopause (menopausal arthritis) |
| Mode of onset | Rarely acute; usually subacute or insidious; often accompanied by migratory pains | Insidious; not accompanied by migratory pains |
| Patient's general condition | Usually undernourished; anemic and chronically ill; frequently slight leukocytosis and slight fever (99°) | Well nourished; frequently obese; not anemic; no fever; no leukocytosis |
| Joint involvement | Symmetrical and generalized; proximal interphalangeal joints especially involved | Usually weight bearing joints; spine, hips, knees; exception: distal joints of fingers; Heberden's nodes |
| Appearance of joints | Early: periarticular swelling; fusiform fingers; Late: ankylosis; extreme deformity; ulnar deviation | Early: slight articular enlargement; Late: more pronounced articular enlargement; ankylosis; slight and never complete; Heberden's nodes |
| Muscular atrophy | Often marked; particularly in later stages | Not characteristic |
| Cutaneous changes | (1) Extremities frequently cold and clammy; skin atrophic and glossy; redness of thenar and hypothenar eminences; (2) Psoriasis occasionally present | No characteristic features |
| Subcutaneous nodules | Present in 15-20 per cent of cases | Not present |
| <i>Laboratory Differentiation</i> | | |
| Agglutination reaction with hemolytic streptococcus | Positive in the majority of typical cases | Never definitely positive |
| Sedimentation rate | Usually greatly increased; tends to return to normal as patient improves | Normal or only slightly increased |
| Roentgenologic appearance | Early: osteoporosis; periarticular swelling and joint effusion; Late: narrowing of joint space; bone destruction; ankylosis and deformities | Early: no osteoporosis; slight lipping at joint margins; Late: marked lipping; osteophytes |

arthritis is essentially a degenerative process involving joint structures at a time of life when other degenerative changes occur. This type does not present the picture of infection as does the first. The patient is nearly always middle aged or elderly and the joint lesions are probably as much a phase of senescence as the graying of the hair.

The accompanying tabulation is a review of one published by Dawson Sia and Boots in 1930.

With typical examples of these two conditions, the differential diagnosis is simple. However at times the distinction may be difficult, especially is this true when osteo-arthritis is superimposed later in life on an already existing rheumatoid arthritis or vice versa. Occasionally this is also true of early cases of rheumatoid arthritis before the agglutination test becomes positive and before roentgenographic changes occur.

Differential Diagnosis Between Strümpell-Marie's Disease and Hypertrophic Arthritis (Osteo-Arthritis) of the Spine

DR JOSEPH L MILLER, Chicago Although the anatomic changes of Strümpell-Marie arthritis were described 100 years ago, accurate descriptions have been given only in the last thirty years. The disease may develop as a complication to a number of infective diseases as atrophic (rheumatoid) arthritis, gonorrhea, typhoid, bacillary dysentery, and influenza. "Like rheumatoid arthritis it is thought to begin in the only synovial membrane in the spine, the small lateral articulations of the transverse processes and the ribs."

The disease shows a marked tendency to ankylosis and osteoporosis in the adjacent vertebrae and it is clinically progressive. Late changes are (1) ossification of the intervertebral ligaments, especially the anterior longitudinal ligament, (2) ossification of the periphery of the intervertebral disk, (3) extension of the spongiosa of the vertebra through the center of the disk, (4) it results in bamboo spine. These changes are irrespective of the infective cause. The cause resembles rheumatoid arthritis. It was frequent in Germany after the war and in veterans' hospitals. Marie believed that trauma played a part. Heredity plays no part.

With regard to hypertrophic arthritis (osteo-arthritis), since man has not become accustomed to the erect attitude the pressure on the disks of the spine causes deterioration and becomes thin and causes mobility and consequent strain to the ligamentous attachments in the periosteum at the vertebral rim. Osteophytes result.

Nerve root pain is the outstanding symptom of ankylosing spondylitis. The disease in the cervical spine causes nerve symptoms in the arms, in the lumbar spine it causes numbness and in the legs loss of power. The dorsal spine involved causes rib ankylosis and loss of chest breathing. The degree of pain depends on the distribution of the inflammation. If gradual, there may be only stiffness with gradual rigidity resulting in a poker back and kyphosis. The muscles are spastic, any jar or strain causes pain. Finally the chest is flattened, the anterior and posterior diameter lessened. A characteristic slow, shuffling, bent-over gait results. The hips show true fusion, sometimes the shoulders are involved but they are rarely ankylosed. The figures of Geilinger indicate that the leg is affected in 61 per cent, the shoulder in 58 per cent, the knee in 44 per cent, the foot in 41 per cent, the finger in 19 per cent, the hand in 18 per cent, the elbow in 17 per cent, the jaw in 17 per cent. The shoulder is held by spasm of the abductors, owing to involvement of the brachial plexus. Fraenkel reports that the ankylosis is bony in the hips. X-rays aid in the diagnosis of ankylosing spondylitis because of the early recognized osteoporosis, the narrowed intervertebral disks and the ossification of the ligaments, quite different from the osteophytes, which are not found in this type of arthritis except in old age.

Osteo arthritis differs in that Schomolard finds osteophytes in 93 per cent of people in the sixth decade. There is rarely pain, if pains are present they are neuralgic root pains but not persistent as in ankylosing spondylitis. The pain is rarely disabling. X-ray examination shows osteophytes. Differential diagnosis is easy because in ankylosing spondylitis 60 per cent of the cases occur before 40. The condition is rare in women. The sedimentation rate is high. Ankylosis of the ribs occurs and a rigid spine is the rule. X-ray examination reveals a bamboo spine with osteophytes absent.

DISCUSSION ON PAPERS OF DR. BOOTS AND DR. MILLER

DR. RUSSELL L. CECIL, New York I believe that it helps to think of the rheumatic type of chronic arthritis as an inflammatory disease and of the other type as a degenerative disease the former associated with inflammation soft tissue swelling exudate and fluid and the latter with bony change no soft tissue swelling and absence of active inflammatory changes—a dry, creaking joint. One thing that is confusing us is the fact that some of these patients with hypertrophic arthritis can go on so long without any pain and then suddenly develop pain. I believe Osgood is right when he says that in hypertrophic arthritis the pain is due in many cases to trauma that is the effect which these bony spurs have on the synovial membrane. If this mechanical irritation is sufficient there can develop a

hydrops in the joint or a villous arthritis, and still it is a long way from the typical picture seen in the infectious joint. Of course, there is no reason why the middle aged patient should not get infectious or rheumatoid arthritis, and he does get it. I recently saw a man, aged 77, who was having his first typical attack of rheumatoid arthritis, with the characteristic fusiform fingers. Theoretically there is nothing to prevent an elderly woman from getting gonorrheal arthritis. She may already have marked hypertrophic arthritis. Heberden's nodes may be seen on the distal phalangeal joints of the fingers, and fusiform swellings on the proximal phalangeal joints. Let us not forget that any irritant if it is sustained will produce hypertrophic changes in the bone. That does not have to be trauma, though trauma is a common cause of it. It appears after fracture. It occurs in joints containing foreign bodies, after infection, in the Charcot joint and in gout. In a patient particularly in beginning middle age, who develops rheumatoid arthritis, it is natural, with the tendency toward osteal changes and cartilaginous degeneration, that with the development of rheumatoid arthritis there will be certain secondary changes in the bone as well. Let us not forget the tendency in certain families toward these bony changes. When I suspect hypertrophic changes in middle aged patients, I first look at the fingers and if I see a Heberden's node I am pretty sure of osteo-arthritis. If I do not see Heberden's nodes, I hesitate to make a diagnosis of osteo arthritis. The agglutination reaction must have some significance. A positive agglutination reaction of hemolytic streptococcus furnishes an important lead in the diagnosis of the disease. It is present in a high percentage of the cases, particularly if the statistics are limited to those patients who have had the disease for some little time. In the early stages it is absent. But with a technician who is used to reading the agglutination test, a very high percentage of rheumatoid arthritis patients will give a positive reaction. Its practical value is in differential diagnosis.

DR. ERNEST E. IRONS, Chicago I suppose we would all agree that one of the characteristic features of atrophic arthritis, including the ankylosing type Dr. Miller described, is infection and that one of the most characteristic factors in the hypertrophic type of osteo arthritis is the group of changes that come with advancing age. There are a number of other factors that are perhaps not quite so clearly associated with one or the other type of arthritis. I think that we ought to develop the idea that was referred to briefly by Dr. Cecil, namely, the tissue peculiarities of the patient himself. This difference in tissue reaction to trauma is characteristic of races, of families, and sometimes of individuals. A surgical operation may in one person heal in a few weeks leaving a line scar with but little redness. In another patient operated on by the same surgeon at the same time a marked keloid may develop. Applying this to arthritis, undoubtedly there are different degrees of resistance to infection in different people. Certainly, different families differ in the incidence of chronic atrophic arthritis. The changes of senescence appear much earlier in one patient than in another. So resistance to infection and the quality of tissue reaction in patients must play a large part in determining whether the patient will have arthritis, and if so, the type.

DR. EDWIN W. RYERSON, Chicago Dr. Miller has shown in his lantern slides the characteristic changes of the various types of arthritis. One significant point is the number who develop arthritis that we have missed in the past. The other point is the chronic ankylosing arthritis, of which in Chicago we have seen a number of examples. I wish to emphasize the importance of applying apparatus to the individual who is beginning to get ankylosis of the spine. If he is not treated by a Taylor brace or plaster jacket or a bivalve stirrup jacket, he is certain to become very kyphotic and a long curve in the spine will occur. For years I have seen an old dentist walking along with his back bent to a right angle simply because no one when he was seen at the early stage of this disease had thought of putting on any apparatus. So the value of orthopedic common sense in some of these cases cannot be emphasized too much. It is worthy of remark that some of the painful arthritic spines can be greatly relieved first by traction in bed if the condition is very acute and secondly by suitable apparatus to hold them upright so as to prevent lateral and anteroposterior

motion of the spine. If these measures are carried out, these patients will be greatly relieved and in the end be definitely benefited by orthopedic procedures.

DR. RUSSELL L. CECIL, New York. I should like to ask Dr. Ryerson how soon braces should be put on those backs. Is there danger of putting them on too soon and losing motion in the back?

DR. RYERSON. If motion is the cause of pain and if it is a spine that is going to ankylose anyway, what difference is it if you put on a brace and do obtain a painless ankylosis of the spine? On the other hand, a rested joint is more likely to recover motion than if allowed to go on without a brace.

DR. LORING T. SWAIM, Boston. I agree with Dr. Ryerson. I believe that early fixation of the spine prevents the process from going too far and producing the bony changes that are seen in the spine. I have one patient in a jacket who was stiff, at the end of five years he is beginning to get back some lumbar motion. Bony ankylosis has not taken place, I believe, because constant trauma was prevented. All the protective muscle spasm goes with support. The tense neck and adductor spasm of the legs disappear at once with adequate support in a jacket.

DR. JACOB S. KOMINZ, Rochester, N. Y. I wonder whether infection plays the same part in causing the ankylosing type of spondylitis that it does in arthritis of other joints. I ran across a couple of cases that have been under observation for several years. One patient was a carpenter who specialized in laying floors. Following a throat infection, though the tonsils were removed, he developed an ankylosing spondylitis which has progressed to marked degree. The other was a service man in a gasoline service station who took a particular interest to see that the cars in his station for greasing were carefully done and worked in the greasing pit himself. This necessitated much stooping on his part. He developed one of the types of ankylosing spondylitis. I wonder whether those who have used the back more actively and persistently than other individuals are predisposed to that type of spondylitis? In doing compensation work one frequently runs across individuals who evidently had slight hypertrophic arthritis of the back, and suddenly, when some injury draws attention to it, have a chronic back disorder that causes a lot of trouble. Secondly, people are going about who have marked evidence of hypertrophic changes in the spine and yet have no symptoms, and only incidentally, when roentgenograms are taken for some other purpose, these marked bony changes in the spine are discovered. I should like to ask how to interpret these cases.

DR. JOSEPH L. MILLER, Chicago. Regarding ankylosis spondylitis, I can easily see how infection can play a role. In most of these cases we have no idea as to where the infection originated. I think from my own experience in the Cook County Hospital, where we have a great many colored people, that by far the most common cause is gonorrhea. This condition may appear in the spine without any involvement of the joints of the extremities. Now, why some patients have pain in osteoarthritis and others do not, we do not know. Anton Fischer says very positively that it is not due to pressure on the nerve roots. It is true that in England workers who handle heavy steel get lumbago. These people may rest up for a week, then return to work and then find that the pain recurs. Osteoarthritis which is usually not a disabling disease, can cause disability in people following certain occupations. One frequently sees osteoarthritis of the knee in women who have become obese after the menopause. The pathologic condition in the knee of late cases of rheumatoid arthritis and advanced cases of osteoarthritis may be almost identical. Nichols and Richardson called attention to this point. In their work the specimens from these two types of cases were so similar that they thought the two diseases were related. These polypoid changes come from the synovia. If there is no synovia left, no polypoid changes take place.

DR. R. GARFIELD SYDER, New York. The classification proposed by Dr. Boots and Dr. Miller seems to be the most satisfactory method outlined to date. However they fail to emphasize the importance of the large group of cases that can be accurately classified only as mixed arthritis. Statistics differ of course, according to location but it has been my experience that at least 50 per cent of the total number of cases treated belong to the mixed group. The importance of properly

classifying these cases lies in the fact that the term "mixed" serves as a reminder in outlining treatment that there is an infection as well as a metabolic element to deal with. Dr. Boots and Dr. Miller state that although the majority of cases of rheumatoid arthritis occur between the ages of 20 and 40 there are cases which occur up to 80 years of age. I would emphasize that whereas in the patients under 30 the tonsils are the most likely source of infection, in the patients between 40 and 70 the foci are usually chronic and not infrequently are silent in character. The sinuses, gallbladder, prostate and genito-urinary tract are the sources most often suspected. It has been my experience, and I am sure the experience of all of us, that the efficient removal of these foci, regardless of the age of the patient, causes an excellent therapeutic result.

DR. M. HENRY DAWSON, New York. I should like to say a word concerning a series of cases of Marie-Strümpell arthritis that I have studied in the past six years. In all there were sixty examples and in general the statistics agree with those of Anton Fischer, which Dr. Miller has quoted. Forty-eight of the cases occurred in males and twelve in females, a ratio of 4 to 1. This curious sex distribution is quite different from that which occurs in rheumatoid arthritis. Nevertheless I believe that the two diseases are essentially the same except for their anatomic localization. In relation to the sex distribution of the two conditions there is one important fact. Just as Marie-Strümpell or rheumatoid spondylitis is more common in the male, so also it is a "purer" disease in this sex. By this I mean that it is more strictly confined to the spine. In the female, on the other hand, there is a definite tendency for the disease to assume a "mixed" form with simultaneous involvement of both the spine and the peripheral joints. I have studied carefully the relationship between gonococcal infection and the development of rheumatoid spondylitis. I have been able to obtain but little evidence to support this concept. One occasionally sees patients with rheumatoid spondylitis who have had gonococcal infection but to prove a relationship between the two conditions is almost impossible. Only two of the sixty patients gave a positive gonococcal complement fixation and in my experience gonococcal infection has not been any more frequent in rheumatoid spondylitis than in many other diseases. Dr. Miller stated that the involvement of the hips and shoulders in Marie-Strümpell arthritis was frequently osteoarthritic in nature. This has not been my experience. In nearly one fourth of the cases there has been involvement of the hips or shoulder joints and roentgenograms have invariably shown that the changes were rheumatoid in nature.

DR. JOSEPH L. MILLER, Chicago. The only description of the hips I found was in Buckley's article in which he described simply the type of picture of osteoarthritis. I found one other reference to osteoarthritis. I am glad to hear Dr. Dawson say that the majority of his cases were really rheumatoid arthritis.

DR. M. HENRY DAWSON, New York. Gilbert Scott of London has shown and it has been my experience, that 90 per cent of all cases of Marie-Strümpell spondylitis show involvement of the sacro-iliac joints.

DR. PHILIP LEWIN, Chicago. I think that Dr. Dawson's statement can be compared with what is seen in spurs of the os calcis. The presence of gonorrhea does not prove that the spur on the os calcis is due to the gonococcus any more than Marie-Strümpell's disease in the spine is due to the same organism.

DR. RALPH H. BOOTS, New York. Realizing that Lord Horder is an honored guest it seems in poor taste to engage in controversy with him concerning my ideas of the etiology of these two types of arthritis. However, I cannot leave you with the impression that their causes are definite in my mind. My statement with regard to osteoarthritis was that "it might be possible that it is due to the summation of joint insults during the entire time of one's life. With regard to rheumatoid arthritis it was stated that the true etiology is not definitely known. However, demonstration of the presence of hemolytic streptococcus agglutinins in the blood of these patients seems to me the most important advance made recently in this disease. This work has been confirmed by a number of investigations and by blindfold tests by Cecil Dawson and others.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Bone Changes in Chronic Fluorine Intoxication.—Bishop adds a case of fluorine intoxication to the four cases reported by Flemming Möller and Gudjonsson. The case was similar in history in that fluorine salts were ingested, the bone changes were identical and the fluorine content of various bones was estimated. The essential roentgen changes are an increase in bone density without alteration of normal bone structure, lack of normal sharpness of the bone outlines, and extension of calcification into ligamentous attachments. These features combine to give one the impression that the roentgenograms have been made with a broad focus tube operating at too low a voltage. The increase of bone density varies from slight blurring and accentuation of the trabeculations, "fleece thickening of the bone laminae," in areas of early involvement, to marked homogeneous opacity, "milk white opacity," with obliteration of bone detail in the most advanced areas. The earliest changes appear in the trunk. As the condition progresses these changes become more marked and the process extends toward the periphery, until in advanced stages the bones of the hands, feet and skull are involved. The characteristic of this increase in density is the preservation of the normal osseous architecture. The appearance is one of normal bone structure but of too much of it. The indistinct margins are the result of extension of calcification into the soft tissues at the attachments of ligaments and muscles. Osteophyte formation with calcification of the ligaments between vertebral bodies is marked. Complete bridging between vertebral bodies is frequent in advanced cases which accounts for the stiffness of the back that is often present. In the pelvis the anterior iliac margins and the pubic and ischial borders show roughening with extension of spicules into the soft tissues. Differential diagnosis is of importance because of the difference in prognosis between this condition and the one with which it is most likely to be confused—osteoplastic metastasis from carcinoma of the prostate. They are similar in that both produce sclerotic bone changes with the spine and pelvis most frequently and extensively involved. In fluorosis the normal bone architecture in spite of the increase in density, the uniformity of distribution of the density, the calcification of ligaments and the absence of a corresponding failure of general health should indicate the benign nature of the condition. A history of long continued exposure to fluorine

ingestion may be difficult to obtain but will establish the diagnosis. In carcinoma of the prostate there is disturbance of bone structure, no matter how dense the sclerosis, areas of destruction can be identified. There is also less tendency to regularity of distribution of the lesions.

Visualization of Minute Gallstones.—Ettinger states that several cases with a history of gallbladder disease have been observed in which roentgenograms taken in the prone position showed apparently normal cholecystograms. Further investigation of these cases by taking roentgenograms of the gallbladder in the upright position with compression technic and aimed exposures showed clearly numerous small filling defects lying close to one another at the fundic end of the gallbladder shadow. The explanation for this advantage of the upright position is that tiny negative shadows caused by the presence of small stones in the dye-filled gallbladder may become easily blurred or erased by the slightest motion, particularly because the stones in the prone position are scattered diffusely throughout the gallbladder. In the upright position, however, the small stones sink by force of gravity to the lower pole of the gallbladder and consequently their aggregation forms a rather large area of increased radiance, which is not easily overlooked, even with slight motion on the part of the patient. As a rule stones of all sizes, whether of opaque or nonopaque quality collect at the lower pole of the gallbladder in the upright position but occasionally small nonopaque stones are found floating freely at a certain level in the bile. The author observed three such cases. In all of them roentgenograms in the prone position yielded no definite information but in the upright position showed clearly a horizontal row of small radiant defects suspended within the contrast bile. The clinical feature of two of these cases was the presence of typical severe gallbladder colic. The third case presented less characteristic complaints. The peculiar phenomenon of stones floating at a certain level makes it evident that the gallbladder may contain bile of different specific gravities at the same time. While layer formation in bile is present in normal cholecystograms, it remains to be determined whether or not it represents a physiologic state of normal bile or occurs only under the unphysiologic conditions imposed by the presence of the heavy iodine atom of the Graham test. The increase of density of the gallbladder shadow after a fatty meal is explained by removal of non-contrast bile from the gallbladder. A faint shadow due to the presence of much noncontrast bile may result in the usual roentgenogram, while a roentgenogram in the upright position reveals a normal, well functioning gallbladder. There are, of course, quite a number of faint shadows that do not change their appearance whether taken in the upright or the horizontal position. They represent the real pathologic group. Thus the upright position permits a helpful differentiation of various types of faint gallbladder shadows. The method should be added to the routine examination in cases in which clinical and roentgenologic observations do not agree.

Liver Extract as Remedy for Roentgen Sickness.—Young gave liver extract to thirty patients suffering from roentgen sickness. For the purpose of drawing valid conclusions, care was taken to avoid psychic factors and changes of technic or dosage. Intravenous injections of 2 cc of the drug were withheld until the patient was definitely suffering from roentgen sickness. Once the liver therapy was started, the dose or volume of radiation was not reduced. The criteria for roentgen sickness were vomiting, which ensued during the treatment or more commonly at a definite time interval after it, and marked nausea between the episodes of vomiting. Every effort was made to eliminate systemic disease or gastro intestinal derangements as causes for vomiting before instituting liver therapy. In most cases it is necessary to give 2 cc daily (provided the roentgen treatments are given daily) if the patient is to be kept symptom free but in certain cases the beneficial effect will last two days. The author does not believe that it makes any difference when the liver extract is given. Most of the patients received it before the roentgen treatment and others from a few minutes to an hour or two after the treatment. Of the sixteen patients who obtained complete relief only three needed more than two injections. Seven patients were relieved of all vomiting, but they complained of nausea at some time during the treatment series. Seven were classified

as failures Twenty-three of the thirty patients, or 77 per cent, were either completely or partially relieved by the drug Liver extract produces an additional beneficial effect in that roentgen intoxication is partially or wholly relieved by its use Listlessness depression, loss of energy and appetite are the principal features of this malady

Transmission of Virus of Equine Encephalomyelitis—In the experiments with *Aedes albopictus* Skuze (a common, semidomestic, oriental mosquito), which Simmons and his associates review, it seems likely that all animals bitten by the test mosquitoes contracted encephalomyelitis. However, one cannot consider this as proved in all instances, since tests for the specific reidentification of the virus were carried out only with tissues from certain animals which had been bitten by mosquitoes of certain lots. If one could be sure that the remaining animals died of encephalomyelitis, it would appear that after inoculation into the four guinea-pigs virus was present in the blood of one or more animals on each of the following six days and that it was ingested by the normal mosquitoes that fed during those days and that, when the six lots of mosquitoes were tested from seven to thirty-eight days later by allowing them to feed on normal guinea-pigs, these animals became infected and died after periods of from four to twenty-nine days. Considering all the evidence, it appears that in each of these animals infection and death were produced by encephalomyelitis virus which had been transmitted by the mosquitoes. However, specific neutralization and pathogenicity tests in normal and immune animals were carried out only with tissues from animals bitten by mosquitoes from three of the test lots. Therefore, the results can be considered only as definite proof that the virus was transmitted by one or more of the three lots of mosquitoes, and additional observations will be required to determine the detailed mechanism of transmission through *Aedes albopictus*.

Experimental Tuberculous Allergic Serositis—Howard and deVeer confirm the observations of others that serous effusions may be elicited in several serous cavities of tuberculous guinea pigs by the introduction of tuberculin into one

of the cavities. The regularity with which allergic sensitization recurred after eliciting gross allergic reactions in these chronically infected animals contrasts strikingly with the difficulty of maintaining such a state in experimental animals sensitized artificially by the injection of various antigens. Well developed fibrous pericarditis can be produced in mildly infected tuberculous guinea-pigs by the repeated injection of tuberculin into the peritoneal cavity. Milder degrees of fibrous change in the peritoneal cavity can be developed under the same circumstances. Chronic fibroid pleuritis can be developed in mildly infected tuberculous guinea-pigs by the repeated injection of tuberculin into the pleural cavity. These are obvious examples of scar formation resulting from allergic reactions, the possibility of which has been questioned. The more heavily infected the tuberculous guinea-pigs, the more extensive and severe was the allergic serositis produced. The reaction, when severe, often proved fatal in from twelve to twenty four hours and under such circumstances the tuberculous lesions were found to be the seat of great congestion and acute cellular infiltration (focal reaction). The sites of recent and subsiding skin tests became inflamed again and sometimes necrotic, as would be expected. In man, adhesions between the serous surfaces are often found. In fact, death is frequently caused by the hampering effect on the heart's movements of these adhesions or by cicatricial tamponade of the heart. Few adhesions developed in the guinea-pigs. They did develop or start to in the animals into which Paterson injected living cultures of tubercle bacilli, representing, in these cases, the organization of surface exudates and the development of tubercles. The degree of inflammatory reaction and the presence or absence of actual infection in serous cavities apparently condition this phenomenon.

Virus Diseases—Rivers sets forth the three possibilities of the nature of viruses. 1 The smallest viruses, e. g., the viruses of foot-and-mouth disease and poliomyelitis, may be inanimate incitants of disease transmissible in series. Stanley believes that the virus of tobacco mosaic is an autocatalytic substance and recently reported that he is able to obtain it regularly in crystalline form. His work is significant, and if his interpretations of it are accepted, progress has been made with regard to the nature of certain viruses. 2 The medium sized viruses, as exemplified by the etiologic agents of yellow fever and fever blisters, may represent forms of life unfamiliar to us. 3 The virus of vaccinia might well be a minute living autonomous organism or a midget in the microbial world, provided the elementary bodies that are infectious and are composed of protein, fats, carbohydrates and ash represent nothing but individual units of the virus. It is generally agreed that viruses regardless of their nature, are intimately associated with the cells injured by them. As certain viruses induce a marked hyperplasia of tissues it is easy to understand why such agents are considered in discussions of the cause of cancer. In spite of the great amount of work that has been carried on in this field the relation of virus tumors to cancer has not been determined. Viruses as a rule compose such a minute portion of the tissue emulsions containing them that it is impractical at present to obtain large amounts of them for administration.

tration as vaccines There is no reason to suppose that the general principles of immunity are not operative in virus diseases

Effect of Potassium Arsenite in Leukemia—Stephens and Lawrence found potassium arsenite an effective palliative agent in the treatment of seven cases of chronic myelogenous leukemia Symptomatic improvement was reported by the majority of patients soon after the administration of the drug was begun In several instances, symptoms referable to the leukemia temporarily disappeared Symptomatic improvement was accompanied by gain in weight, reduction in the size of the spleen and improvement in the blood picture Soon after the toxic dose of arsenic was reached, the total leukocyte count began to fall sharply and in many instances approached the normal value Decrease in the total white blood cell count was accompanied by a diminution in the percentage of immature cells, so that the white blood cell picture as a whole approached normal The degree of hematologic improvement varied from patient to patient, and in the same patient with successive courses of the drug Anemia which was present to some degree in all cases, was favorably affected As a rule, increase in the red blood cell count and hemoglobin did not occur until a significant reduction in the total white blood cell count had taken place Although there was originally no significant decrease in platelets in any of the patients studied, a favorable response to the arsenic therapy was usually accompanied by an increase in the platelets, easily detected in the smears Omission of the drug resulted, in a few weeks in a return of the symptoms, increase in the size of the spleen and increase in both the total leukocyte count and the percentage of immature cells Although there is apparently no danger of inducing bone marrow aplasia, the danger of other serious manifestations of arsenic poisoning must be kept continually in mind in giving over long periods the large doses of solution of potassium arsenite necessary to induce symptomatic and hematologic remissions in leukemia Unless frequent and careful observations can be made this form of therapy should not be used The beneficial results observed in leukemia are apparently due in large measure to an inhibitory effect on the abnormal process of granulopoietic activity resulting temporarily in a tendency for the involved structures to return to normal This inhibitory effect is apparently incomplete and temporary symptomatic and hematologic relapse occurs after prolonged administration of the drug in adequate dosage The response in individual patients treated with solution of potassium arsenite compares favorably with the reported symptomatic and hematologic response of patients adequately treated with roentgen therapy In considering the relative merits of the two therapeutic procedures, several points should be borne in mind Solution of potassium arsenite is relatively cheap is readily available and does not require complicated and expensive equipment or special technical experience Frequent clinical and hematologic observations are essential regardless of the method of therapy employed Arsenic is merely a palliative measure with temporary effect as is the case with roentgen therapy It is probable that arsenic may be used most advantageously in conjunction with or alternating with irradiation

Oxygen and Thyroid Ablation in Heart Disease—Barach and his co workers employed preoperative operative and postoperative oxygen treatment as an adjuvant to ablation of the thyroid in twelve cases of heart disease In patients with congestive failure, their circulation efficiency was improved by the preoperative period of residence in an oxygen chamber During the operation itself and for a time following it oxygen therapy tended to prevent the development of oxygen debt and anoxic shock There were no operative deaths The authors reviewed the physiologic effects of oxygen therapy in cardiac decompensation Its helpfulness in this condition has added further evidence in support of the authors' belief in the value of this form of therapy Their interest has been aroused chiefly in severe cases of congestive heart failure of rheumatic etiology in the absence of an active rheumatic process In two cases of this type followed for more than two years the gain in cardiac efficiency has been striking Perhaps the treatment of angina pectoris by thyroidectomy should be restricted to patients who have troublesome anginal pain in the absence of clinical and electrocardiographic evidence of an advancing sclerosis of

the coronary artery In two cases of this type the clinical improvement that ensued completely justified the operation Three patients, two with cardiac pain and one with congestive failure and cardiac pain, were not benefited One patient having congestive heart failure was not improved and died six months later The remaining four were improved, the time elapsing since operation being insufficient to permit giving a reliable estimate of the degree of benefit

Intervertebral Disks and Pain in Back—Sashin declares that the pathologic changes of the intervertebral disks observed at necropsy vary from small herniations of the disk through vascular infiltration of the disk substance, fibrous replacement of the elastic tissue, brown degeneration, and finally shrinkage, narrowing and calcification of the entire disk As a result the disks lose their flexibility and resilience They become firm immobile and less resistant to the stress and shock of functional activity When a disk is narrowed anteriorly, the normal lumbar lordosis is diminished and the articular facets are slightly separated When the lumbosacral disk is narrowed, the lumbosacral angle is increased and there results a considerable separation of the articular facets As a result of the malalignment of the facets arthritic changes take place, with consequent muscle spasm pain and often impingement of the fifth lumbar nerve root resulting in sciatic pain down the leg Clinically, the diagnosis of a narrowed intervertebral space is made from the roentgenograms, especially the lateral and oblique views Seven cases in which there was roentgenographic evidence of a narrowed intervertebral space are reported Pain in the lower part of the back was a constant complaint In some cases there was associated sciatic pain down the leg The treatment consisted in reestablishing the normal lumbar lordosis under general anesthesia and supporting the spine by means of a plaster-of-paris jacket

Chronic Toxicity of Carbon Tetrachloride—Through the exposures of white rats monkeys and guinea pigs to controlled concentrations of carbon tetrachloride for eight hours

a day, five days a week, for a period of ten and one-half months the Smyths and Carpenter observed that 100 parts per million carbon tetrachloride vapor is a safe concentration for continuous exposure of workmen throughout the day, and day after day. It is believed that 1,000 parts per million is safe for periods up to half an hour a day with lower concentrations the rest of the day, provided the day's average does not exceed 100 parts per million. This concentration agrees with the conclusions of Davis. An animal continuously exposed to amounts of carbon tetrachloride of from 50 to 400 parts per million soon regenerates originally damaged liver cells and somewhat later regenerates damaged kidney cells while the exposure continues, the regenerated cells being more resistant than the original cells. It is believed that the same is true of human beings. It is argued from this that in most cases men working with carbon tetrachloride under reasonable conditions of ventilation and care increase their resistance rather than their susceptibility. Of ninety-six men exposed to carbon tetrachloride in industry, tests showed none who could be considered seriously or even unmistakably injured by the solvent vapors. Nineteen of these men had worked more than ten years with the solvent, one of them twenty-five years. No worker need be injured by exposure to carbon tetrachloride if intelligent planning and supervision are available and if physical examinations are made. Standard dry cleaning machinery now available will keep the concentration below 100 parts per million, and by provision of adequate exhaust ventilation other processes can be similarly guarded, usually without undue expense and perhaps with a saving of solvent.

Dissociation of Acidfast Organisms—Steenken and Landau describe an organism similar to the one (M strain) isolated by Lyle Cummins and Williams from the sputum of a girl suffering from a chronic pulmonary illness. The present organism (I P strain) was isolated from the sputum of a patient presenting an almost identical clinical picture to that of Cummins case. The object of the authors' studies was to determine whether they could dissociate the I P and M strains and to compare the behavior of the variants on artificial mediums and whether they possessed any pathogenicity for laboratory animals. They have included in this study a third strain of nonpathogenic acidfast organism isolated by one of them from a BCG culture brought to them by Drs. Frappier

from Birkhaug's laboratory, University of Rochester. The strain was dissociated into at least two variants possessing distinct topographic and other biologic characteristics. One of the variants in the early stages of colony development appeared to be white but as they aged, when left at room temperature and exposed to light, invariably developed chromogenicity. All the variants propagated at 37.5 C. as well as at 20 C., however, at the former temperature their growth was more profuse. Non-acidfast forms could be demonstrated in very young and again in older cultures. They were all pleomorphic. These studies definitely show that environmental conditions play no small part in morphologic variation. They were nonpathogenic for laboratory animals except in the case of the M strain which displayed some pathogenicity for mice and rabbits. It may be that larger doses are required or it is possible that their virulence will be enhanced after several animal passages. They were weak antigens producing complement fixing antibodies with some degree of specificity. Specific tuberculin could be prepared from each strain and animals inoculated with the strain reacted more strongly to the homologous than to the heterologous tuberculin. The significance of the so-called nonpathogenic acidfast organisms isolated from human sources is still a speculative one. It seems that they cannot be regarded merely as saprophytes, although there are certain similarities, viz., their behavior on artificial mediums, the production of chromogenicity, the pH curves and the pleomorphic morphology in different environments. It seems highly probable however that under certain circumstances, these organisms may be responsible for the production of disease man.

Experimental Study of Uretero-Intestinal Implantation.—Hinman performed ureteral implantation, simultaneously bilateral except in two instances, on fifty-three dogs by ten different methods. The intestine was opened at the time of the operation in all but the five dogs on which the method of Higgins was used. In forty dogs, variation of technic was slight. Thirteen dogs died of peritonitis. The experiments were not planned solely for the study of peritonitis. The poor results obtained were fully anticipated in most cases. The significance of suturing and overlapping of the intestine to necrosis and leakage, fully demonstrated by Halsted and others, needs no confirmatory study. The results indicate that the risk of peritonitis is much greater by some methods than by others. Peritonitis rarely occurs as a result of contamination with the contents of the intestine or with urine at the time of operation when the obvious precautions are followed. Leakage from the intestine or the ureters after operation is the common cause. Leakage occurs when the anastomosis is faulty and the

ureter has not been sutured securely into the opening of the intestine. An oblique submucous insertion of the ureter is much safer than direct insertion. Leakage occurs when anchoring sutures tear or slough out. The only safe layer for suturing is the submucosa, the use of which carries the greater risk of penetration of the lumen. Leakage occurs when a suture punctures the intestine (fecal fistula) or the ureter (urinary fistula). It occurs with necrosis of a portion of the intestine or of the transmurular portion of the ureter. The blood supply of the intestine or ureter must not be tied off by sutures or impaired by too great constriction. Infection of the abdominal wound from contamination at the time of the operation is more imminent than peritonitis. Abscesses in the abdominal wall may rupture to the inside and produce peritonitis. The incision should be walled off more securely than the intestine is packed off, and gloves, drapes and instruments should be changed before closure is carried out. Implantation by any method which requires that the intestine be opened at the time carries the considerable risk of localized inflammation both of the intestine and of the ureter. A localized peritonitis may clear up or become general. A local abscess may be absorbed or it may rupture into the cavity and then produce peritonitis. A periureteritis may produce urinary obstruction or the infection may ascend to the kidney. Localized inflammation may lead to anemic necrosis of the intestine or ureter, which will permit leakage, and peritonitis will be the result. Inflammation at the site of implantation may result from temporary leakage after operation, and probably this is the most frequent cause. The operative technic must prevent local contamination and secure a watertight anastomosis.

Unrecognized Postoperative Infection.—Touroff recommends that the abdomen of patients suffering from early postcholecystectomy hyperpyrexia associated with shock of unexplained origin should be examined repeatedly and carefully for evidence of peritoneal irritation. Examination should include firm percussion and palpation over the lateral portions of the lower chest and costal margin. Local tenderness thus elicited is a most valuable presumptive sign of infection of the subphrenic space, such infection together with infection of the subhepatic space constituting the most common suppurative intra-abdominal complications of cholecystectomy. Spontaneous pain in the shoulder or tenderness on palpation in the general region of the trapezius ridge, if present, is likewise of great confirmatory significance. If no evidence of the existence of intraperitoneal suppuration can thus be found, roentgen examination should be performed. Anteroposterior and lateral roentgenograms of the chest are taken at the bedside, with the patient supported in the sitting position. These must include not only the pulmonary fields but the diaphragms and the subphrenic regions as well. Roentgenograms taken in full inspiration and expiration should be compared for evidence of diaphragmatic immobility and elevation. Such roentgenographic studies will also definitely establish or exclude the presence of pneumonic consolidation of sufficient extent to account for the clinical course. In the absence of adequate pulmonary or subphrenic alterations on roentgen and physical examination exploratory peritoneal puncture is indicated in an attempt to demonstrate the presence of a suppurative intraperitoneal lesion. In the event of negative results on aspiration, one should promptly aspirate the subphrenic space in the usual manner. If the patient has been operated on under spinal anesthesia if the diagnostic procedures mentioned fail to reveal the presence of intraperitoneal or pulmonary infection, suppurative meningitis without characteristic manifestations may be present and lumbar puncture should be performed. Gastric aspiration is recommended in all obese individuals, since unrecognized gastric dilatation may obscure the evidence of a suppurative lesion within the upper part of the abdomen. Supportive therapy is of added significance, in that the longer the patient survives the greater is the probability of arriving at a diagnosis and perhaps of saving life. The actual treatment of any infective lesion which may be discovered constitutes a general surgical or medical problem, depending on its nature. Treatment should be prompt and vigorous in the hope of occasionally saving the life of a patient whose prognosis otherwise is hopeless. The general attitude in regard to such cases should be modified as clinical manifestations may not be due to "liver shock" but

may be produced by unrecognized fulminating infection. Adequate postmortem examination constitutes the only means of corroborating the diagnosis of "liver shock."

Regional Enteritis (Nonspecific)—Meyer and Rosi report one case of regional enteritis of the jejunum and seven of the ileum. Four of the patients had acute regional enteritis. In three the process resolved spontaneously and in one it progressed to the chronic stenotic phase. There were four patients with the chronic stenotic type of regional enteritis. Two had lesions of the terminal ileum. One patient, who had a lesion of the terminal ileum complicated by a large abscess, developed following drainage of the abscess a persistent external intestinal fistula which required resection. The fourth patient had a regional jejunitis. The pathologic anatomy is that of a nonspecific inflammation. The acute regional enteritis consists of an infiltration of the intestinal wall by acute inflammatory granulation tissue with extensive ulceration of the mucosa. This process may resolve spontaneously or progress to the chronic phase. The chronic forms of regional enteritis are usually associated with a hyperplasia of the intestinal wall by a nonspecific inflammatory granulation tissue which contains granulomas, foreign body giant cells and an excessive amount of connective tissue. Linear ulcers of the mucosa are present along the mesenteric border of the intestine. In the terminal ileum these ulcers penetrate through the intestinal wall and form sinuses that lead into the mesentery, which is frequently the site of an abscess. Internal and external intestinal fistulas may develop and lead from the involved intestine to an adherent loop of intestine or the abdominal wall. The pathogenesis of this regional inflammation of the intestine is not known. Clinical and pathologic studies have failed to demonstrate any evidence of tuberculosis, actinomycosis, syphilis or Hodgkin's disease. The symptomatology of regional enteritis varies with the different phases of the pathologic process and with the location of the lesion. The treatment varies with the phase of the pathologic process. Acute regional enteritis limited to the intestine and not associated with thickening of the mesentery may resolve spontaneously. If, however, the mesentery is thickened and indurated, it is probable that ulceration of the mucosa has extended into the mesentery, spontaneous resolution then is less likely to occur, and a short-circuiting operation or a resection is indicated. Chronic regional enteritis with stenosis is best treated by resection or a short-circuiting operation. When complicated by an external intestinal fistula resection of the involved intestine with the fistulous tract is necessary to close the fistula.

Transillumination of the Breast—Wilson asserts that transillumination of the breast provides an additional method for differentiation between various lesions. The procedure is so simple and frequently yields information of such great value in diagnosis, prognosis and treatment that no breast examination may now be considered complete without it. Early difficulties which were encountered have been solved by the development of a water-cooled lamp which throws a strong light without heating the skin applicator so that one may carry out an extensive examination without causing the slightest discomfort to the patient. The appearance of the normal breast and of breasts harboring hematomas, solid or cystic tumors, duct papillomas and duct carcinomas, the traumatic breast and the breast with the bleeding nipple are discussed and also pictured graphically.

Radiosensitivity in Relation to Time Intensity Factor—McWhirter uses the term intensity to mean the number of roentgens per minute. In the study of different intensities other variables, such as the total period over which the treatment is given and the total dosage, must be kept constant. The system of dosage used was that recently described by Paterson and Parker, and practical homogeneity over the treated area was obtained by selecting distributions giving a variation not exceeding plus/minus 5 per cent. In carrying out 140 separate experiments between 500 and 600 actual applications of radium or x-rays were necessary. The response of normal tissues was determined by irradiating healthy skin, and then later the effect on superficial tumors was studied. Twenty-four cases were studied. Twelve of these were rodent ulcers, and from the point of view of response to 4,500 roentgens there are four other cases available—one wart, one tuberculous lesion and two slowly growing carcinomas. Eight cases of carcinoma were treated with 5,000 roentgens. Continuous irradiation would appear to be ideal, and a theory has been advanced in which it is stated that radium may owe its superiority over x-rays to the fact that its application is generally more continuous. The following evidence is put forward in attempting to assess the value of the hypothesis. The rate of mitosis in the tumors studied must be very slow, for their rate of growth was slow. In the case of epitheliomas the mitotic cycle will be shorter but even in the more rapidly growing ones it is uncommon for the tumor to double its size in one week. Assuming however that an epithelioma did double itself in one week, the average interval for mitosis to occur in any one cell would be one week, for the daughter cells will grow to the size of the parent before dividing. If such an epithelioma is irradiated continuously, the dosage delivered during the sensitive phase might be sufficient to kill it, and the premitotic sensitive period might appear to be very important. If, on the other hand, high intensity is used and the tumor is irradiated for only thirty minutes or less each day, it follows that many cells would not be irradiated during the sensitive phase, which is probably comparatively short. Yet it has been shown that a tumor can be destroyed by the latter method. But it is clear that in these experiments the cells did not all divide in one week, and if the treatment time had been prolonged in order to catch each cell during its sensitive phase a stage might have been reached at which sufficient dosage could not have been delivered during the period of sensitivity. In another group of experiments, tumors were made to disappear with a continuous irradiation of only two hours. It would follow therefore that the important difference between tumor cells and normal tissue cells is one of variation of sensitivity of the adult cell and that this variation is independent of the premitotic sensitive phase.

- Viruses in Etiology of Skin Diseases—During the last five years Brain has carried out investigations on four skin diseases of virus origin: herpes zoster, varicella and molluscum contagiosum. The infectivity of human warts and molluscum

contagiosum is in accord with clinical observations. Attempts were therefore made to demonstrate the presence of antibodies in the serums of patients with multiple lesions. With an antigen prepared by grinding up curetted wart material with sodium chloride solution, serums from five cases of multiple warts were examined by the complement fixation reaction. No specific fixation was obtained, and precipitin tests with both heated and unheated antigens were negative. Serums from six patients with multiple mollusca and from one individual who had been given a series of inoculations with formaldehyde molluscum material were tested, in only two cases were positive results obtained. Precipitin and agglutination tests were also made, and here again the results were negative. Transmission experiments have also been performed with material from cases of dermatitis herpetiformis. Of ten cases examined, fresh bullous fluid was obtained in only four. The undiluted fluid was inoculated intradermally in the shaven skin of the flanks and the plantar skin of the hind feet of guinea-pigs. Two of these specimens were bacteriologically sterile, and the animals inoculated with these developed no lesions. The other two fluids contained staphylococci and streptococci and, with these herpetiform lesions were produced in the plantar skin of the inoculated animals; no lesions appeared in the hairy skin. The presence of a streptococcus in the material used may be of significance. In only one instance was a bacteriologically sterile filtrate found to be infective, although attempts to produce lesions in the skin of the guinea-pig with the streptococci obtained from the human lesions were unsuccessful. Sterile bullous fluid from a case of pemphigus vegetans was inoculated into a guinea pig, a rabbit and mice without result. Inoculations of guinea-pigs with material from five other cases of bullous eruption urticarial or erythema multiforme, were unsuccessful. One of these bullous fluids contained staphylococci and streptococci; the other four were sterile. The serums from eight cases of psoriasis have been tested with various antigens prepared from psoriatic scales but complement fixation and precipitation reactions were entirely negative. It was thought that artefact bullae superimposed on recent lesions of psoriasis or lichen planus might contain the hypothetical virus but no specific antigenic reactions were obtained with such material.

The Dental Prop. W. W. Muir—p. 1062

Cause of Hypertension in Preeclamptic Toxemia.—Browne and Dodds studied the blood pressure of several infants of hypertensive mothers. Most of the infants were born by cesarean section and in every case the blood pressure of the mother was at a very high level just before the section was

performed. The pressure was measured in both mother and child by the same instrument. In the infants a specially small armlet had to be employed. A rise of blood pressure was not observed in any of the cases. It might be supposed that, if the cause of the hypertension in preeclamptic toxemia and other hypertensive conditions in pregnancy were a substance, hormone or otherwise, circulating in the mother's blood, this substance would diffuse through the placenta to the fetal circulation and that the infant would then have a raised blood pressure at birth. The authors conclude that, whatever causes hypertension in preeclamptic toxemia, it is not a substance that is capable of passing across the placenta into the fetal circulation.

Brain and Lung Abscess and Benign Spontaneous Pneumothorax Complicating Otitis Media.—Allison and his collaborators cite the case of a person who had both brain and lung abscesses and lateral sinus thrombosis as complications of otitis media and who regained normal health. Following lung abscesses and empyema on the right side there occurred on the left side a complete spontaneous pneumothorax. Although this was not associated with any infection of the pleural sac or effusion into it, the evidence points to its having arisen as a result of an infective process in the lung. Since the pneumothorax occurred six weeks after the internal jugular vein had been tied, it is possible that it was caused by a lesion in the lung which had been in existence at least six weeks. Whether this etiology is of wider application in benign spontaneous pneumothorax is uncertain, but it is sufficient to suggest that the commonly accepted cause should be subjected to careful scrutiny and inquiry made for any hint of a recent infection of the lung. By the time the lung had reexpanded there was no roentgen evidence of the original causative factor.

Ionization Treatment of Hay Fever.—Shields shares the general prejudice against the introduction of drugs through the skin by ionization, first because their action in the quantities in which they are applied must be very slight, owing to the flushing action of the blood and lymph streams; secondly because they are more efficiently administered in properly controlled dosage by other routes. The problem of intranasal ionization is however different for here the effect is entirely local and the nasal mucosa can be impregnated with an insoluble substance which remains local for several hours. On theoretical and practical grounds intranasal ionization of zinc sulfate is a justifiable and valuable method of treating hay fever and vasomotor rhinorrhea. It has been suggested that the beneficial effects of intranasal zinc sulfate ionization may be due to the sedative action of anodal galvanism and not to the impregnation of the mucous membrane with zinc in ionic form. Therefore the author has given four applications to

patients with hay fever, using gauze soaked in sodium chloride solution and employing the same amount of current for the same time without the patient being aware of any alteration in the technic. The characteristic symptoms of increased salivation and conjunctival injection were not seen, and there was no delayed reaction and no improvement in the original condition following this treatment

*Technic of Repair of Diastasis of Abdominal Rectus Muscles F D'Allaines and A J Contiades—p 922

Thrombosis of Inferior Vena Cava Case. R Fontaine L Israel and S Pereira—p 928

Repair of Diastasis of Abdominal Muscles—D'Allaines and Contiades believe that repair of diastasis of the rectus muscles should be undertaken only when symptoms are produced which cannot be controlled by support. Usually the surgical technic used in the treatment is similar to that employed for postoperative herniation. In the technic which the authors employed, however, it was unnecessary to expose the body of the muscles, and only the internal border of the aponeurosis was sutured. In performing this suture they press back the median intermuscular portion gradually by means of the aponeurosis, which produces progressive invagination. This progressive invagination behind the aponeurosis avoids the peritoneum and the muscular tissue. In cases of marked diastasis, however, the bringing together of the two sheaths is often difficult. Under such circumstances, as Pozzi has shown, the advantage of two or three liberating incisions at the external edge of the sheaths often allows the usual plan to be followed. The authors, however, have never had to use this device. In the eight patients observed for from one to four years after the operation, the results were satisfactory and the tissues solid enough to allow a normal life without functional disorders.

*Blood Serum in Internal Leishmaniasis P Giraud Claude and R Bernard—p 876

Anal Fistulas and Their Excision G Cabanée—p 878

Blood Serum in Internal Leishmaniasis—The diagnosis of internal leishmaniasis, according to Giraud and his collaborators, can only be suggested by the clinical examination. On the other hand, search for the specific parasite is often difficult and necessitates maneuvers such as splenic puncture, which are accompanied with certain danger. In an attempt to determine whether the blood serum in any of its aspects might aid in diagnosis, the authors examined the serum from fifty-three patients with human kala-azar and a number of dogs with internal leishmaniasis, and experimentally inoculated dogs. Of thirteen cases of human kala-azar, the total protein was found to be above normal in nine instances and was found in all the dogs affected with natural leishmaniasis. In three dogs inoculated peritoneally the proteins were slightly lowered immediately after the inoculation, returned to normal in from three to six months, and were raised within a year after the inoculation. It can be concluded they believe, that the blood proteins are lower at the onset of the disease but are raised after the disease has become established. The proteins remaining soluble in a solution of anhydrous sodium sulfate are normal or diminished in internal leishmaniasis. The albumin-globulin ratio was often low and sometimes inverted. The authors also investigated a number of flocculation reactions with different substances. The specificity of the flocculation reaction with ureastibamine is great. It produced a positive result in dilutions of 1 to 1,000 but is not absolutely constant and gives little help in following the evolution of the disease. The formol-gel reaction is, because of technical simplicity, ease of interpretation, constancy and specificity, the most important of the serologic reactions for the diagnosis of internal leishmaniasis.

*Boring Cancers of Face. R Imbert—p 331

Urethroplasty for Congenital Strictures H Godard—p 374

Technical Varieties of Gastrectomy and Their Indications C Clart—p 387

Boring Cancers of the Face—Imbert discusses, in numerous case reports, the cutaneous epitheliomas of the face which are often called boring cancers. He concludes that mistakes of treatment of cutaneous epitheliomas do not constitute the essential cause of their evolution toward erosion. There is a strong clinical presumption, in the absence of histologic certainty, that there is an individuality to epitheliomas, which, because of general or local peculiarities, especially in the nature of nutrition, regulates the reciprocal relations between epithelial and conjunctival tissues and therefore determines the degree of erosion. Such tumors represent from 5 to 10 per cent of all the cutaneous epitheliomas. In the author's statistics the spinocellular group was in the majority. He believes that in the treatment of these conditions physical therapy should be abandoned and wide surgical excision adopted as the treatment of choice.

*Aspects of Benign Aseptic Suppurating Meningitis During Childhood E Glanzmann and D Heller—p 541

*Role of Hypophysis in Genesis of Diabetes Mellitus F Mamzer—p 546

Thrombosis of Veins of Fingers Case W Jadassohn—p 549

New Calibration of Hemometer A Alder—p 549

Benign Aseptic Suppurating Meningitis—Glanzmann and Heller call attention to the fact that there are entirely benign serous and even suppurating meningitides, and that for this reason it is advisable to be cautious in rendering an unfavorable prognosis in cases presenting meningitic symptoms. There is an acute onset with meningitic symptoms. The spinal fluid shows meningitic changes, that is, there may be a slight increase in the mononuclear cell elements, while the fluid remains clear (serous meningitis), or there may be a noticeable suppurating turbidity. Direct examination as well as the culture method reveal that the cerebrospinal fluid is sterile (aseptic meningitis). The course is relatively short, benign and without secondary complications. Etiologic factors in the form of local disorders (otitis, sinusitis, pneumonia, intoxication) or in the form of systemic diseases (acute or chronic infectious diseases) are absent. After reporting the clinical histories of five cases of their own observation, the authors point out that aseptic meningitis develops chiefly in children and occasionally even in nurslings. They discuss in detail the symptomatology, the hematologic aspects, the clinical course, the differential diagnosis and the therapy. With regard to the latter factor they say that for diagnostic as well as for therapeutic reasons repeated spinal punctures are advisable, for these often effect a reduction in fever and rapid cure. They also prescribe methenamine and aminopyrine. In the most refractory case they resorted to the intravenous injection of a bacterial protein preparation. In order to avoid collapse, it is advisable to administer caffeine or other cardiac stimulants.

Hypophysis and Diabetes Mellitus—Mamzer points out that the so-called sthenic diabetes of older persons, which is usually accompanied by obesity and arterial hypertension should be differentiated from the so-called asthenic type of younger persons, which is accompanied by emaciation. He maintains that the sthenic type of diabetes mellitus is of hypophyseal origin and cites the following factors in support of the hypophyseal genesis: (1) the great similarity of the symptomatology of this form of diabetes with the glycosuria that occurs in Cushing's disease (hypophyseal basophilism), (2) the great clinical differences between this type of diabetes and the types that are caused by hypofunction of the islands of Langerhans, namely the experimental pancreatic diabetes and the diabetes of young persons, which results in emaciation, (3) the disappearance of experimental pancreatic diabetes following removal of the anterior lobe of the hypophysis and the production of a diabetes by the continuous administration of extract of the anterior hypophysis. Clinical observations (in Cushing's dis-

case) and the fact that the injection of extract of the anterior hypophysis results in hypertrophy of the adrenals indicate that the hypophysis exerts its action at least partly by way of the adrenals. The author shows further that the arguments which are advanced in favor of a unitarian, insular genesis of diabetes mellitus and which stress the transitional forms between the asthenic and sthenic forms of diabetes, as well as the histologic aspects of the latter form, do not take sufficient account of the complex nature of the diabetic disturbance of the metabolism. Experiments with continuous insulin medication show that the primary disturbance in the hormone equilibrium involves all the secretory glands that regulate the carbohydrate metabolism. The author suggests that, if the thyrogenic and nervous forms of glycosuria are disregarded, diabetes mellitus can be pathogenically differentiated in the following forms: 1 Primary pancreatic diabetes, which includes experimental pancreatic diabetes, asthenic diabetes of young persons and diabetes that develops in pancreatitis, in destruction of the pancreas by tumors and in brown diabetes. 2 Primary hypophyseal diabetes, which includes (a) eosinophilic diabetes (in acromegaly) and (b) basophilogenic diabetes, namely, the diabetes in Cushing's disease and the sthenic form, which is accompanied by hypertension and obesity and occurs in older persons.

Colloidal Thorium Dioxide Used as Contrast Medium in Hysterosalpingography. E. Benassi—p. 681

Development of Premature Infants—Giuffrida says that premature infants will develop normally, without receiving any especial treatment if they have no congenital diseases, weigh more than 2,000 Gm at birth and are given the same care and feeding accorded normal infants born at full term. The author made studies on the action of extracts of the anterior lobe of the hypophysis and of the blood from pregnant women in forty premature infants who weighed less than 2,000 Gm at birth. Twenty infants were given intragluteal injections of citrated blood from women in the seventh and eighth months of pregnancy and with a negative Wassermann reaction. The injections were given every other day in doses of 5 cc, which contain about 50 units of prehypophyseal hormones and $2\frac{1}{2}$ units of ovarian hormones. The other twenty infants received daily intragluteal injections of the content of an ampule of prehypophyseal extract (an arbitrary dose of the commercial preparation used). All the infants were born spontaneously or by cesarean section. They were kept under identical conditions, that is, in incubators at 28 C. (82.4 F), breast fed or, when unable to nurse, fed mother's milk with a teaspoon or a sterile rubber catheter. The treatment was established a few hours after birth and the infants were kept under observation for at least two weeks. The author concludes that the most important factors in the care of premature infants are the maintenance of the infants in the incubators at an even temperature, because they are extremely sensitive to temperature changes, and feeding them with sufficient amounts of mother's milk. The injections of blood of pregnant women are harmless but apparently give no useful results. Prehypophyseal extracts not only are useless to the infants but seem to be harmful.

Contrast Medium in Hysterosalpingography—Benassi states that the use of thorium dioxide colloids in hysterosalpingography is of advantage when the injection of iodized oil is difficult because of the presence of uterine anfractuositities or of retained fluids in the uterine cavity as well as in cases in which a detailed study of the uterine mucosa is indicated. Thorium dioxide colloids give also satisfactory results in hysterosalpingography of the pregnant uterus. The danger of the production of fatty emboli does not follow the use of thorium dioxide colloids in hysterosalpingography. However it is important

to have in mind that in the presence of ulceration of the uterine mucosa or in cases of loss of tissue of the mucosa the injection of thorium dioxide is followed by rapid absorption and entrance of thorium into the circulation and frequently selective accumulation of it in the liver and spleen.

Thermo-Isolated Graduate for Centrifugation of Fluids. V. Nicoletti—p. 96
Rapid Method of Flocculation for Diagnosis of Syphilis. F. Ritz—p. 99

Weltmann Seroreaction in Clinical Diagnosis—Di Benedetto and Stornello made determinations, by means of the Weltmann serum coagulation test, of the electrolyte threshold of the blood serum of persons suffering from leishmaniasis, malaria and several other diseases, as well as in pregnancy. They used three additional test tubes, one of which contained distilled water and the other two 0.05 and 0.02 per thousand calcium chloride solutions (solutions at a lower concentration than those used in the original technique). The authors conclude that the normal electrolyte threshold stands at 0.4 and 0.5 per thousand calcium chloride solutions. The threshold increases in the blood serum of persons suffering from exudative inflammatory conditions and diminishes in that of persons suffering from fibrosis and disturbances of the liver and the reticulo-endothelial system. There is no electrolyte threshold in the blood serum of persons suffering from leishmaniasis, in which flocculation takes place even in distilled water. Probably there is a relation between Weltmann's test and the reticulo-endothelial system. The latter is concerned with the maintenance of the physicochemical equilibrium of the blood serum and the changes of the electrolyte threshold point to rupture of the equilibrium which in different degrees of intensity, may be common to several diseases.

Cystic Dilatation of Appendix. Appendicular Mucocele. Case. O. V. Ribeiro—p. 113
Tuberculosis of Breast. Case. Sylvio Heilborn and B. Benchimol—p. 121

Partial Sphincterectomy in Megacolon—Etzel says that the pathogenesis of sphincter achalasia (failure of one or several of the sphincters of the large intestine to relax) due to disturbances of the Auerbach plexus in megacolon is proved. The treatment by partial resection of the involved sphincter or sphincters (Correia Netto's technique) gives satisfactory results. The operation consists in resecting a third of the circumference of the involved sphincter in all its extent including a segment of 2 cm of the muscular layers above the sphincter in order that all the circular fibers of the given sphincter are divided by resection and none of them are left forming an unbroken ring. Resection of the internal sphincter of the anus is performed with the patient under epidural anesthesia by the following technique: curved incision of the skin at 1.5 millimeters on left side of the anus beginning and ending at the perineal raphe, dissection of the internal and external sphincter of the anus, exteriorization of the internal sphincter through the operative wound and resection of the sphincter in a third of its circumference up to the muscular layers, reconstruction of the operative wound and drainage. Resection of the pelvic rectal sphincter is performed with spinal anesthesia by infra-umbilical median laparotomy with the following steps: traction of the pelvic colon (having the third sacral vertebra as point of reference for localization of the pelvic rectal sphincter), performance of a 10 cm. longitudinal incision on the sphincter and resection of the latter in a third of its circumference. It is advisable to take care during this step not to injure the mucosa. The gap in the colon left by resection is covered with a flap from the omentum which is sutured to the border of the gap for peritonization. The wound is closed without drainage. Recovery was obtained in two patients by partial resection of the

internal sphincter of the anus in one case and of the pelvic rectal sphincter in the other case. Recovery of the patient was obtained in a third case by partial resection of both the pelvic rectal and the internal anal sphincters.

*Grave Hemoptysis Due to Sequestrums of Ribs Migrated to Lung Case A Amorim—p 339

Complementary Thoracoplasty A Farnesi—p 347

Grave Hemoptysis Due to Sequestrums of Ribs—Amorim reports a case of grave hemoptysis in a 7 year old child in whom auscultation and all tests for tuberculosis were negative. The Wassermann test was positive. A diagnosis of syphilitic osteitis of the rib was made with the hypothetical diagnosis of wound of the lung due to sequestrums from the osteitic rib. The osteitic segment of the rib was resected and, during the operation, it was discovered that two sharp fragments from the rib had migrated to the lung and were injuring the organ. The wound from the sequestrums was the cause of hemoptysis. The pieces of rib that were recovered from the lung were 3 and 7 cm. long and 3 mm wide. They were sharp and corresponded to the space found in the piece of resected rib. The operative wound was closed with drainage and the child placed under antisyphilitic treatment. The patient recovered.

*Basal Metabolism and Specific Dynamic Action of Proteins in Liver Diseases J Andréu Urrea and J Lozano—p 323

Difficulties in Experimental Studies of Ulcerous Colitis F Gallart Monés and P Domingo Sanjuán.—p 331

Action of Proteins in Liver Diseases—Andreu Urrea and Lozano determined the basal metabolism in patients suffering from diseases of the liver parenchyma before and one, two, three and six hours after administration of 200 Gm of roasted meat and 25 Gm of bread. The authors conclude that the consumption of oxygen is increased and the specific dynamic action is diminished in most patients suffering from diffuse diseases of the liver parenchyma. The results confirm those of experiments on the same subject, previously reported in the literature, and point out the important part that the liver, in association with other endocrine, metabolic, sympathetic and electrolytic factors, plays in the regulation of the specific dynamic action of proteins; they support the theory of deamination as the cause of the specific dynamic action of proteins.

New Opinions and Experiences on Development and Treatment of Urinary Calculi E. Brack—p 807

Mistakes in Treatment of Bone Fractures M. Kaspar—p 813

Dry Treatment or Fatty Ointments in Skin Diseases—Mulzer stresses that the general condition of the skin, particularly its secretory action, must be given consideration when it is to be decided whether an eczema should be treated by means of an ointment or by a dry method. In seborrheal patients, that is, in those in whom the skin, especially of the face, is oily and shiny, has comedones and a tendency to acne, and in whom the hair is oily so that it requires frequent washings, the use of ointments, oils and soft pastes is not advisable because it is not well tolerated. The application of fatty ointments or pastes apparently results in secretory stasis and irritations. In such patients a dry treatment is advisable. The author uses chiefly a zinc mixture which contains zinc oxide, talcum, glycerin and water, but he also approves of a ready prepared so-called dry salve which, in addition to zinc oxide and talcum, contains also siliceous earth which increases the drying effect. The colloidal form of the constituents insures a uniform and nonirritant consistency. However in the patients in whom skin and hair are especially dry, ointments and soft

pastes are the best remedies for eczemas. In this connection the author calls attention to the fact that patients with neurodermatitis, in whom the skin is usually extremely dry, tolerate ointments well. He concedes that, in addition to observing the type of skin, it is also necessary to adhere to the general rules regarding the use of dry preparations. They are indicated in inflammatory nonweeping but strongly scaling skin diseases but are contraindicated in weeping skin disorders, in which moist applications are advisable. In acne and rosacea, dry treatment should always be tried first.

Acute Cerebral Edema in Internal Medicine L. Kubnel—p 669

Idiopathic Psoas Abscess Case O. Wichtl—p 671

Treatment of Acute Mercury Intoxication—Fulde emphasizes that in mercury poisoning the first aim should be to remove the part of mercury that has not yet been resorbed by means of gastric irrigation, by a suspension of animal charcoal and subsequent administration of 20 per cent solution of magnesium sulfate. After that, diuresis should be stimulated, the organism should be freed as much as possible from the decomposition products of protein, circulatory weakness should be guarded against, and the organism should be supplied with the necessary quantities of water and calories. In order to realize these aims, venesections are done every second or third day, infusions of hypertonic (20 per cent) solutions of dextrose and of physiologic solution of sodium chloride are given and cardiac stimulants are added according to need. The dextrose exerts a favorable effect on the heart, vessels and hepatic parenchyma, it increases the defense mechanisms of the organism and also has a reducing action on the mercury compounds. The author describes the histories of three cases which prove that the aforementioned measures produce favorable results even in severe cases of mercury nephrosis and renal insufficiency.

*Pharyngitis of Measles with Protective Extract from Placentas of Normal Mothers H. G. Huber—p 446

Autohemotherapy in Diseases of Childhood—Kellhammer investigated the efficacy of autohemotherapy in seven children thirty with infectious diseases of the urogenital tract (acute and chronic pyurias, cystitis, cystopyelitis), twenty-four with infectious diseases of the respiratory tract nine with suppurating skin diseases (pyoderma, cutaneous abscesses, phlegmons, erysipelas, furunculosis) and twelve with other

disorders (osteomyelitis, recurrent infections in dystrophy, disorders of the middle ear with septic temperatures, meningococcic meningitis and so on). The author analyzes these groups and reaches the conclusion that autohemotherapy is not as effective as has been stated by some. However, particularly in chronic pyurias, which are not caused by deformities, autohemotherapy is effective in a large percentage of cases. Many other infectious diseases are likewise favorably influenced. Moreover, the treatment has the advantage that it is simple and without danger. The results of autohemotherapy are by many ascribed to the fact that protein bodies of all types increase the antibodies and that by the disintegration of the homogeneous protein which has been changed into a foreign one, the globulins are increased. The author thinks that, even if it has not been definitely proved that globulins are antitoxins, they are at least vehicles of immune bodies. He assumes that the process is not a specific immunizing action but only a form of nonspecific therapy. At any rate to explain the action of autohemotherapy it must be assumed that the blood undergoes some change. It is noteworthy that this form of "protein" therapy never results in sensitization or anaphylactic manifestations.

Prophylaxis of Measles with Placenta Extract—Huber reports that extract from the placenta of normal mothers was used during an epidemic of measles for the protection of thirty-seven children who had other disorders most of them having diphtheria. Administered in quantities of 10, 15 and 20 cc it always proved harmless and produced an effective protection against measles. Its prophylactic value was equal to that of convalescent serum. Since the placental extract is always available, it is especially suited for medical practice and in this respect it has the advantage over the convalescent serum.

*Viale's Reaction for Presence in Blood of Substances Related to Epinephrine. Katharina Loeb —p. 651

Attempt at Treating Patient with Pemphigus by Means of Active Immunization A. Binger —p. 653

Therapeutic Use of Cobra Toxin—Favorable results reported by other investigators induced Kirschen to try cobra toxin on patients with inoperable or relapsing cancer who had severe pains, and also on patients with neuralgia and neuritis. The technic of the treatment is somewhat difficult because the optimal dosage must be determined in each individual case. Subthreshold doses have either no effect or only a slight one, whereas excessive doses increase the pains and produce severe general reactions. To be sure, the severe pains that frequently appear at the beginning of the treatment are often the first sign of an improvement. The author usually begins the treatment with 0.5 cc of the cobra toxin. He recommends subcutaneous injection in the region of the supraspinous fossa or in the upper gluteal region. At first the injections are given at three day intervals. Later the intervals can often be prolonged to eight days or even two weeks. The author employed the cobra toxin in fifteen patients with gastric cancer with pulmonary, three with rectal and two with mammary cancer. He gained the impression that the roborating action of the cobra toxin is chiefly due to its analgesic effect. It is of great importance for the usually cachectic and undernourished patients that it is possible to counteract the pains with a remedy which does not like morphine, reduce the appetite and the normal defense powers of the organism. The author would not like to dispense with cobra toxin in inoperable or relapsing cases of carcinoma.

Viale's Reaction—Loeb points out that Viale regards his reaction as suitable for the demonstration of epinephrine in the blood. However, there is a considerable difference in the epinephrine concentration of the blood detected with Viale's method and the concentration that is detected with other methods. Viale's values being abnormally high. In view of this fact the author suspected that Viale's reaction indicates not only epinephrine but also a number of substances that are chemically related to it and therefore she decided to search for such sub-

stances, particularly for the derivatives of pyrocatechic acid. On the basis of her investigations she reaches the conclusion that Viale's reaction cannot be regarded as specific for epinephrine, but that it indicates also a number of substances that are related to epinephrine, namely, derivatives of pyrocatechic acid. She also found that the quantitative outcome of Viale's reaction is the same in healthy persons and in hypertensive and diabetic patients. The author observed an increase in Viale's reaction in two out of four schizophrenic patients with severe insulin shock, in whom the insulin had been given for therapeutic purposes. She detected the highest values in a typical case of Cushing's syndrome but in another case there was no such increase.

Newer Hormone Preparations in Treatment of Menstrual Disturbances E. Klasten —p. 626

Case of Sexual Pseudo-Infantilism. A. Moessner —p. 634

Treatment of Varicose Syndrome—Nobl discusses the varicose complex particularly with regard to treatment and prevention of serious complications. His observations were made in a department in which from 1500 to 2,000 patients with varicose veins were treated every year. He pays attention chiefly to the obliteration treatment by means of solutions of dextrose or of sodium chloride. He emphasizes that this treatment should be strictly ambulatory. Patients who are accustomed to standing should in the course of the obliteration treatment, never rest longer than the time required for the night rest. During the day, wearing elastic bandages is advisable. He observed cases in which obliteration treatment could be given several weeks or months after the last thromboembolic relapse. But although a wider field has been found for the obliteration treatment of varicose veins there are also conditions in which it is contraindicated such as in patients with decompensated cardiac defects, in severe renal disturbances and in advanced metabolic disorders. Moreover, in deep thrombosis the obliteration treatment is likewise contraindicated. The author shows that vasography and palpation are the only reliable methods for the diagnosis of a deep thrombosis. He discusses Neuda's studies on the problem of embolism, which indicated that constitutional factors play a part and that the administration of liver extract acts as a prophylactic against thrombosis.

Malaria and Allergic Reactions—Shirokogorov believes that in the evaluation of the pathologic alterations in malaria one should take into consideration, in addition to the constitution of the patient and the virulence of the parasite, the strikingly altered reactions of the organism under the influence of the malarial virus. These allergic reactions manifest themselves morphologically by a hyperplasia of the reticulo-endothelial system, accumulation of lymphocytes in the liver, petechial hemorrhages and microscopic areas of necrosis in the brain in cases of malarial coma. The author describes what he terms the hepatolienal medullary syndrome which manifests itself by a hyperplasia of the liver, spleen and the bone marrow. He has observed it in 8 per cent of his postmortem material (1100 necropsies). He has studied the question of allergic alteration on the part of the malarial patient to other diseases, in particular to tuberculosis and pneumonia. He has encountered pneumonia in 117 out of 800 necropsies performed on patients dying of acute or chronic malaria (15 per cent). In the same material there were only thirty-nine instances of tuberculosis (less than 5 per cent). Thirty-four of these were cases of acute malaria, which means that thirty-four individuals suffering from chronic pulmonary tuberculosis had contracted malaria. Here tuberculosis was the primary and malaria the

secondary disease. This leaves five cases (0.5 per cent) in which tuberculosis developed in a malarial patient. The author concludes that active pulmonary tuberculosis is seldom encountered in chronic malarial patients and that malaria does not activate old tuberculous foci. The coexistence of the two diseases was observed in only 5 per cent.

Chronic Malaria—On the basis of 10,000 malarial patients observed in the course of thirteen years in the dispensaries of Odessa, Korovitskiy maintains that chronic malaria does exist in a moderate climate where reinfection is not possible. He disagrees with the optimistic views of Rieu, Marchout and Muehlens, who state that malaria in a moderate climate is always curable in from one to two years. In his material not more than 40 per cent were cured at the end of four years. It was his experience that the tropical form was more likely to end in a cure at the end of that period than the milder and more common tertian form. The chronically ill did not present the grave picture seen in the tropical regions. The spleen rarely attained great size and cachexia was not present. He takes exception to the view that diagnosis of malaria is permissible only when the plasmodia can be demonstrated in the peripheral blood. He has observed many cases in which in the course of eight or nine years from forty to sixty examinations of the blood for parasites were negative. The same patients in the course of an acute exacerbation exhibited a few parasites in the blood or, in the absence of parasites, gave a positive melanoflocculation test. Among frequent manifestations of chronic malaria in the Ukraine are the disorders of the nervous system, particularly of the peripheral and the vegetative divisions. The possibility of occurrence of eye disease, particularly neuroretinitis, in the late, chronic stages of malaria was established by the observation of Goldfeder and Moldavskaya. Among the not infrequent disturbances of the endocrine system the author observed symptoms of Addisonism, hypothyroidism, hyposexualism and dysfunctions of the pancreas and the hypophysis. The author speculates on the problem of why a certain number of malarial patients are not cured. He advances the theory that there are two types of malarial infection: the reactive and the nonreactive. The manifestations in the first are sharper, the paroxysms are more pronounced and the spleen is much enlarged. Such cases frequently terminate in a permanent cure. In the second group the phagocytic reaction on the part of the reticulo-endothelial system is less pronounced, the paroxysmal attacks are less frequent and less severe, and the spleen is very little enlarged. These cases, as a rule, go on to the chronic stage.

Subcutaneous Oxygen Therapy in Pneumonia—Fishenson believes that the amount of oxygen absorbed into the pulmonary alveoli when administered by the inhalation method is insignificant. This must be particularly true in croupous pneumonia because of the occlusion of pulmonary alveoli. In the past ten years he has treated 200 cases of croupous pneumonia by the method of subcutaneous injection of oxygen. The dose injected varied from 200 to 800 cc. This may be given twice daily in the severe cases and daily or once in two days in milder cases. In children the initial dose was 50 cc., while the maximum dose did not exceed 200 cc. Danger of embolism is minimized by the fact that oxygen is readily soluble in the blood. He concludes on the basis of clinical observations and animal experiments that oxygen introduced subcutaneously is absorbed and gives rise to oxidizing processes, much the same as it does in the lung, serving in fact as a sort of complementary vicarious 'subcutaneous respiration'. The oxygen thus absorbed enters the circulation and is partly absorbed by plasma, while the rest combines with the hemoglobin. Subcutaneous oxygen therapy appears to be particularly effective in the grave cases of pulmonitis accompanied by cyanosis, cardiac weakness and pronounced intoxication. The favorable effect of this therapy is exerted on the respiration and the function of the cardiovascular system. Dyspnea and cyanosis tend to disappear, the blood pressure rises and the cardiovascular system functions more vigorously. The effect of oxygen is strikingly reflected in the lowering of the viscosity of the blood. The author considers subcutaneous oxygen therapy an effective method of combating the toxic-infectious state but not a specific therapy in pneumonia. The technic of administration is simple, safe and harmless.

- Mimic Ectropion of Upper Eyelids. S. Holth.—p. 520

Fibrinolytic Ability of Hemolytic Streptococci—Waaler's tests of throat cultures from patients with angina and scarlet fever in the acute stage, by Tillet and Garner's method showed fibrinolytic strains in all cases, and fibrinolytic streptococci were often isolated from throat cultures of scarlet fever patients on discharge. Fibrinolytic strains were derived from cases of empyema, pneumonia and septicemia. From throat cultures of twenty-one persons without throat infections eight hemolytic strains were isolated, one of which was fibrinolytic. Study of the antifibrinolytic substances in plasma from well and sick persons rarely revealed antifibrinolysins in well persons. In cases of positive antifibrinolysin reaction in which no definite infection is established, it is suggested that the reaction may depend on a more chronic infection which has not manifested itself clinically. The author says that to determine whether the scarlet fever patients who during the course of the disease for a longer or shorter time present positive antifibrinolysins are more gravely affected by the disease than those with negative reaction calls for a closer investigation, in which the fibrinolytic ability of the strains as well as the antifibrinolytic ability of the serum must be titrated. A positive antifibrinolytic reaction will in most cases point to a streptococcal infection, but the reaction is not certain in this regard. A particular interest is attached to the relation of the antifibrinolysin reaction in infectious arthritis if the reaction, though nonspecific, will allow differentiation of pathogenically different types.

Paget's Disease—Three cases agreeing with the original description of this disease are reported, two in women with the characteristic changes in the nipple and carcinoma in the deep tissue and one in a man with changes in the axilla and carcinoma in the deeper tissue. In the fourth case described, however, originally considered Paget's disease because of localization and certain superficial resemblances in microscopic structure, there were changes particularly in the middle layer with comparatively well preserved basal layer and formations resembling clumped cells, with no tumor, and it is regarded as identical with or closely related to Bowen's disease. In Hval's opinion the designation Paget's disease should be reserved to cases in which there is carcinoma in the deeper tissue.

Bowen's Disease—After presenting two typical cases of Bowen's disease in men aged 63 and 73, Hval discusses three additional cases. The first of these was in a man with disease of the nipple first diagnosed as Paget's disease but believed to be Bowen's disease because of the characteristic picture and absence of a tumor in the deep tissue. The second patient, a woman, aged 65, operated on for cancer of the uterus sixteen years earlier, with a history of Bowen's disease for twenty years, died from primary cancer of the lung. She had used arsenic for years. The third patient, a man, aged 49, with a history of Boeck's sarcoid for thirty-two years and of Bowen's disease for fifteen years, had for years been treated with arsenic for long periods. Two years before death a tumor developed in a plaque on the thigh. After radium treatment a new tumor appeared in the same place, with gradual signs of metastases to the spine. Postmortem examination revealed a tumor of walnut size and metastases to the spine, pleura, ribs and lymphatic glands. Microscopic examination revealed that the tumor was a round cell sarcoma. The regional lymph nodes showed carcinoma metastases and signs of metastasis from the sarcoma. The last two cases are believed to point to a special predisposition for malignant tumors.

RESISTANCE IN TUBERCULOSIS

CHAIRMAN'S ADDRESS

JAMES ALEXANDER MILLER, MD
AND
ISRAEL RAPPAPORT, MD
NEW YORK

The diminution in the death and morbidity rate from tuberculosis is a very remarkable epidemiologic fact. With it has been associated also a marked decrease in the percentage of the population which responds to the tuberculin test and a definite change in the character of the disease. These changes have been noted not only in this country but in the greater part of the civilized world, and while they have been most rapid in recent years they have been gradually going on through several generations.

The underlying causes of this situation have been the subject of considerable speculation. While it cannot be denied that the protection from infection afforded by the better segregation of open cases is a definite factor and that also the improvement in the economic and social status of the people should be considered, still it would appear that a changed resistance to tuberculous infection is a very important factor.

The subject of resistance to tuberculosis has been the object of extended animal research as well as other studies. It is our purpose to attempt to interpret existing knowledge of the subject, looking toward its better understanding. This would appear to be needed, because many current ideas on this subject are very hazy and in general fail to express a clear conception of the role which this factor may play in the epidemiology of the disease.

According to our conception four main factors may be distinguished in the resistance to tuberculosis as manifested both in the individual and in the group as represented by the family and the race.

These factors may be divided into the specific and the nonspecific. Under the specific factors we would list acquired resistance, inherited resistance and accumulated resistance, which is really the combination of the other two. The nonspecific factors may be designated as constitutional fitness, by which is simply expressed the well known fact that some individuals do not become sick as easily as others and applies to many other conditions as well as to tuberculosis.

ACQUIRED RESISTANCE

On first infection with tuberculosis the immediate reaction of the body is nonspecific but sets going a specific immunobiologic process by which resistance to

the disease is eventually acquired. As this resistance succeeds in overcoming infection it becomes increasingly more efficient through an ability to destroy the bacilli and thus to halt the progression of the infection. This acquired resistance manifests itself in tuberculosis by what is termed allergy, which is clinically recognized by characteristic tissue reactions to tuberculin.

It is important to emphasize that the method of action of this type of resistance is by the destruction of the tubercle bacilli or by eliminating them from the body by the process of softening. This destruction of tubercle bacilli, though protective in purpose, unfortunately involves an inflammatory reaction with the liberation of toxins and consequent disease-producing complications, which may be very severe or even fatal.

The milder forms of this reaction, however, tend not only to destroy the bacilli but at the same time to build up a resistance to subsequent infection, and when these infections are periodically repeated a very real degree of resistance to each new infection is thereby developed.

INHERITED RESISTANCE

In our effort to understand the remarkable changes which have occurred in the epidemiologic evolution of tuberculosis we are unable to escape the conclusion that succeeding generations which have been exposed to tuberculosis do not react in the same way as those not so exposed. This would appear to imply that some inherited change in the reaction of the individuals of later generations has occurred because of the experience of the preceding ones, and that consequently something in the nature of increased capacity to acquire resistance has been passed on through inheritance.

We do not pretend to know just how this occurs. We are aware of the prejudice against the idea of the inheritance of acquired characteristics. We may also speculate as to whether the changed resistance of the child of the new generation may be a characteristic acquired *intra utero* from the mother.

Our own hypothesis is that, since recent evidence suggests that resistance depends largely on the reaction of the tissues to the various chemical components of the body of the tubercle bacillus, the quality that is transmitted is a chemical one or at least one of increased potentiality to a certain chemical adaptation.

But in any event we believe that there is a very definite factor of inherited resistance which may explain many of the problems in tuberculosis as it is seen in individuals and as it is exemplified in families or in races.

We would conceive of this type of resistance as being a specific power to inhibit the growth of bacilli at the very outset of infection, and to those who possess it the need of acquiring resistance to destroy multiplying

bacilli in the body does not exist or at least is less urgent. Possessed of this type of resistance, the individual does not need to go through the slow process of acquiring specific resistance with its implications of a disease-producing degree of allergization. The infection or lesion in such an individual will remain slight or ephemeral according to the degree of specific resistance that has been inherited. We would suggest that in countries where tuberculosis has existed for many generations this factor alone is sufficient in many individuals to prevent the occurrence of disease from the minimal dose which goes with the usual inhalation infection.

The amount of specific resistance which can be transmitted by any individual to his progeny can only be that degree which is possessed by the individual himself. But it is our conception that here too each new infection

NONSPECIFIC CONSTITUTIONAL FACTORS IN RESISTANCE

In addition to the specific factors in resistance already discussed, there are also variations due to fundamental constitutional differences between individuals.

It is well known that some individuals do not become sick as easily as others. This difference is perhaps best described as the natural constitutional fitness of the individual. It applies to every vital function and to many diseases and includes as far as tuberculosis is concerned a particularly important function, that of the power of serogenesis, which may be defined as constitutional fitness in relation to immunobiologic reactions.

That this constitutional factor comes largely through inheritance there can be no doubt, but it has no direct relation to previous infection either in the individuals

or in their progenitors. Recent evidence indicates that one is dealing here with a potentiality for resistance and, as far as the serogenic fitness is concerned, that this develops in the individual by a process of maturation with increasing age. This factor operates in the individual or group which comes in first contact with tuberculosis and affects the ability to acquire resistance, that is, it determines his self-allergizing power. By the same token it also affects the store of inherited resistance of the individual, which is subject to lapses with the fluctuations of the general vitality of the individual under the effect of various untoward influences of a lifetime, such as age periods (infancy, puberty) and the effect of intercurrent disease or pregnancy, of impaired nutrition, of severe or prolonged

Schema of levels of resistance. I illustrates how the character of infection and disease is modified by individual differences in resistance. II illustrates how the mortality and morbidity are modified in the group as the resistance rises with successive generations.

will still further develop his acquired resistance and that this additional resistance may be added to the store of specific resistance which this individual will possess and which may be passed on in this enhanced degree to the next generation. The combination of the inherited specific resistance and the acquired specific resistance would give the completed resistance which we would term our third factor, namely, accumulated specific resistance.

ACCUMULATED SPECIFIC RESISTANCE

The first factor, namely, the inherited resistance, which we have defined as the power to inhibit the growth of tubercle bacilli in the body, has thus become progressively increased by the addition of acquired resistance through successive generations, so that it is theoretically possible that a state of comparative immunity to ordinary doses of infection may ultimately be obtained. But, as far as is known, no human individual ever becomes absolutely and completely immune.

economic or emotional stress. Thus it is noted that great variations in the potentiality to develop specific resistance occur dependent on a general nonspecific characteristic which is called constitutional fitness.

APPLICATION OF THESE PRINCIPLES TO THE GROUP

The same general principles hold for the group and for the individual. Differences in the racial and individual evolution of tuberculosis are based on the same factors, namely, differences in accumulated specific resistance. The resistance of the race depends on the level in the immunity scale on which the majority of the individuals rest, and races will rise in this scale according to past tuberculization. In races which have been tuberculized through succeeding generations the inheritance factor is probably the most important one so that, in some members of such a race, resistance is perhaps nearly absolutely complete and in the vast majority it prevents more than a slight and ephemeral reaction to the infection. In those who develop disease

the character of the tuberculosis is of a much milder type than would otherwise be the case

On the other hand, in races which have only recently come in contact with tuberculosis or races which show a genotypic inferiority as regards immunizability to tuberculosis, it is increased susceptibility that is inherited. This is responsible for the increase of mortality in the generation following the first contact with the disease. It is only when the inheritance factor reaches an immunizing degree on its upward scale that mortality and morbidity turn downward. The remarkable phenomenon of persistently high morbidity with conspicuously low mortality in some very long and thoroughly tuberculized races such as the Jews is an indication of the effect of unfavorable social and economic conditions which act through the nonspecific factors in diminishing the effect of the specific factors.

APPLICATION OF THESE PRINCIPLES TO THE INDIVIDUAL

The accumulated specific resistance, as represented first by the inherited factor which prevents the multiplication of the bacilli in the body and secondly by the acquired factor which through allergy protects against reinfection by the power to destroy the bacilli, will determine in the individual the character of his response to the infection.

In what we call virgin soil, characterized by lack of both inherited and acquired resistance, an immediate critical situation is produced, so that, if overwhelming disease is to be prevented, allergic resistance must be acquired with extraordinary rapidity. The slower this process takes place, the more likely is the development of severe or directly fatal disease. This accounts for the acute types of tuberculosis in virgin soil.

If, however, a considerable amount of inherited resistance exists, this prevents the multiplication of the bacilli at the site of infection and allows time for the development of acquired resistance, which may be able to take care of the comparatively small number of bacilli which develop in the body under such circumstances. As exogenous inhalation infection is always in a minimal dose, the presence of this type of resistance will often tend to localize the lesion and prevent the development of disease. If, however, bacilli multiply in the body either because of the large dosage of infection or the lack of specific inherited resistance to prevent their multiplication, endogenous reinfections occur in the body, often in very large doses, and the power to overcome this type of infection depends on the response of the specific allergic resistance which the individual may develop.

Consequently, depending on the level in the scale of inherited resistance at which they are born and depending on their particular ability to acquire allergic resistance at the time of infection, different individuals evolve different tuberculous processes. The less inherited resistance the individual may have, the more he must require if he is to overcome disease while those born with a high inherited resistance sufficient to prevent multiplication of bacilli immediately on first invasion will develop an infection of a very ephemeral character. Thus is explained the wide range of transitions between the rapidly progressing fatal disease which develops in virgin soil, on the one hand and the evanescent type of infection which is so mild that it may be entirely unnoticed, on the other. Between these two extremes are all the kaleidoscopic variations in the clinical manifestations of tuberculosis.

How they may be analyzed according to the interplay of the various possible combinations of inherited and acquired resistance is indicated in table 1. And how these levels of resistance may affect the character of the disease both in individuals and in races is schematically illustrated in the accompanying chart.

THE INTERPRETATION OF ALLERGY

In addition to our application of these principles to the behavior of tuberculosis in individuals and in groups it seems desirable to discuss certain other interesting phases of the general subject of resistance and first the interpretation of allergy.

We as clinicians are particularly familiar with allergy as applied to tuberculosis in connection with the clinical response of individuals to the tuberculin test. That this is a specific allergic response is now well known, but what its presence or absence may imply or what the variations in degree of its reaction signify is still a matter of serious difference of opinion.

An individual who has never been infected will not respond to tuberculin, allergy is absent. On the other hand, there is increasing evidence that many individuals

TABLE 1—Interplay in Tuberculosis of Inherited Resistance and Acquired (Allergic) Resistance

| Inherited Resistance | Acquired (Allergic) Resistance | Resulting Process |
|----------------------|--------------------------------|------------------------------|
| High | Good | Evanescent infection |
| Fair | Good | Infection without disease |
| Low | Good | Localized disease (phthisis) |
| None | Medium | Generalized disease |
| Low | Medium | Localized disease |
| Fair | Medium | Infection without disease |
| High | Poor | Localized disease |
| Fair | Poor | Generalized disease |
| Low | Poor | Severe generalized disease |
| None | Poor | Fatal generalized disease |

This table indicates that the disease is generalized and severe when both inherited and acquired resistance are low or when either one of them is very low while the other is only fair, that the disease is mild and localized when either the inherited or acquired resistance is high while the other is at least fair, that no disease follows infection when both inherited and acquired resistance are fairly high, that the infection is of the evanescent type when both inherited and acquired resistance are the highest possible.

who have been infected may lose their response to tuberculin. This type of tuberculin-negative individuals behaves very differently from the type characterized by virgin soil. It is probable that these individuals have undergone an infection so ephemeral that their allergy is very evanescent and may at times remain altogether undetected.

According to our concept, this, for example, would be the case with individuals who have a very high inherited resistance with good constitutional fitness. On the other hand, we see instances of negative tuberculin reaction which definitely show an absolute lack of resistance, such as are seen in the end stages of progressive disease or in connection with certain other acute conditions such as measles. These cases are on the other end of the scale, their failure to develop allergy is not because it is not needed but because there is an absolute inability in the individual to develop it. Or if in other individuals, the constitutional fitness is very poor and the inherited resistance is very low, there may be also a lack of self-immunizing power to develop allergy, which may exhibit a negative tuberculin reaction in the presence of extensive disease with a very poor prognosis.

On the other end of the scale may be cases showing a very prompt and severe inflammatory tuberculin reaction. Thus by no means should be interpreted as necessarily indicating a very severe and progressive disease, it is much more apt to indicate a very prompt and perhaps quite efficient allergic response which is called for because in that individual the inherited resistance may have been quite low. Between these two extremes appear all the variations of degree of allergic response as shown by the tuberculin test, which may be interpreted in connection with our conception of constitutional fitness and inherited resistance, as indicated in table 2.

It is necessary to keep clearly in mind the fact that allergy and immunity are two altogether different properties, although they are each a part of the same process by which resistance to tuberculosis is produced in the group as well as in the individual. If it is understood that allergy as a manifestation of acquired resistance develops not only according to need but also with the self-immunizing power of the individual, it becomes clear why in practice allergy often appears entirely dissociated from immunity. In fact, a high degree of resistance, as already shown, may be present in asso-

this disease occurs the infection must be opposed by acquired allergic resistance, which at best can only destroy or eliminate the bacilli that are already in the body. If this is successful, it amounts to arrest or healing of the lesions. But opportunities for reinfection are numerous and subsequent relapse frequently occurs. As acquired resistance increasingly develops, successful resistance and healing occurs and the bacilli become walled off in lesions in which they may remain viable for long periods of time, so that liability to relapse must persist until the individual brings up his resistance to such a degree that he can entirely and persistently inhibit the multiplication of bacilli in the body. Not infrequently we see cases of simultaneous healing or even complete absorption of numerous lesions in various portions of the body, which appears to depend on some change in that individual which specifically enables him to get rid of his disease and to heal the process. We would suggest that the explanation of this phenomenon may be that it occurs just when the accumulated resistance of the individual reaches the immunizing level of specific resistance.

THE RELATION OF RESISTANCE TO SPECIFIC THERAPY

Ever since the tubercle bacillus was discovered, the goal of all research has been to develop a specific cure which will successfully and completely combat the effect of this infection. Although this goal is still far distant, we believe that the most likely path leading to it is in this field of specific resistance. Much experimental work in animals has aroused hopes in this direction. That resistance to new infections can be modified by previous inoculations of mild or nonvirulent tubercle bacilli has been demonstrated. But their failure to attain more definite results may be due to the fact that in animals the inherited factor, which we conceive to be predominantly operative in man, is absent, and that further progress in specific treatment along the lines of artificially modifying resistance may depend on a better understanding of this phase of the problem.

CONCLUSIONS

We are offering our concept of resistance in tuberculosis in the hope that it may assist in explaining some of the puzzling epidemiologic and clinical questions that exist in tuberculosis. Part of this concept, particularly that of the role of inherited resistance, may appear to be hypothetical. But since this theory has helped us to correlate a great many heretofore incomprehensible facts of our experience, we hope that possibly it may point the way to future research and finally to a better understanding of this complicated and difficult subject.

133 East Sixty-Fourth Street

TABLE 2—*Interpretation of Allergy*

| Allergy | Constitutional Fitness (Self Immunizing Power) | Inherited Resistance |
|---------|---|-------------------------|
| 0 — + | good | ++ + |
| + + | | ++ |
| + + + | | + |
| + | fair | ++ + |
| + + | | ++ |
| + + + | | + |
| + | poor | ++ + |
| + | | ++ |
| + — 0 | | + |

This table indicates that a low level of allergy may be associated with both high and low inherited resistance; that a very high level of allergy is mostly associated with low inherited resistance; that the level of allergy depends just as much on the need dictated by the resistance inherited as it does on the constitutionally conditioned power of the individual to immunize himself.

ciation with a low degree of allergy, and in the same individual there may be a low degree of allergy at one time and a high degree at another. In practice the amount of what we have termed accumulated resistance can be estimated only by its effect. There exist no means of distinguishing or separating the two components of accumulated resistance, for while the tuberculin reaction directly indicates only the allergic response, this in turn is indirectly affected by the inherited factor. Thus one cannot be sure whether the level of allergy, as revealed by the response to the tuberculin test, is the measure of the one or the other factor. In general therefore, conclusions based on the response to the tuberculin test may be very misleading.

THE EFFECT OF RESISTANCE ON HEALING PROCESSES

It is not our object to discuss the effect of resistance on healing processes in any great detail, but it must be obvious that, if the principles which explain the development of various types of disease are sound the same principles must be at work also in the various types of healing that are seen in tuberculosis. Disease as we understand it depends to a great extent on the multiplication of the bacilli in the body, which takes place because of inadequate inherited resistance, and when

Oxygen Want in the Stratosphere—At about 12 000 feet altitude, there are usually objective signs of oxygen want which become progressively worse as altitude increases such that at from 15 000 to 25 000 feet unconsciousness occurs and at 20 000 to 30 000 feet the organism dies. Through the use of pure oxygen oxygen want can be prevented up to an altitude of about 37 500 feet. At that altitude pure oxygen gives a partial pressure of oxygen in the lungs equivalent to that of the normal atmosphere at sea level. Above that altitude oxygen want again develops and unconsciousness will occur at about 4 000 to 50 000 feet. It was thus evident that other means of supplying available oxygen would be required.—Armstrong H G. The Medical Aspects of the National Geographic Society U S Army Air Corps Stratosphere Expedition of Nov 11 1935. *J Aeronaut Med* 7 55 (June) 1936.

PATHOGENESIS OF TUBERCULOSIS

MAX PINNER, MD

ONEONTA, N. Y.

The characteristics inherent in bacillus and host which in their interaction determine the development of the disease are far too numerous to be discussed in the limited space at my disposal. As far as the bacillus is concerned, the pathogenically most important ones are its high resistance, its singularly complete adaptation to parasitic life, its relative virulence, the dosage of infection, and its chemical constituents which stimulate or alter more or less specifically different tissue elements. In the human host there are to be considered constitution with all its variables, such as intercurrent disease, age and state of nutrition, specific immunity, allergy environmental conditions and what has been called the accidents of localization. This quite incomplete enumeration of pathogenically important factors is made only to emphasize their great multiplicity. Each one of these factors has been made the subject of elaborate study, often, unfortunately, with the result that a major or even exclusive importance has been attached to the particular subject under scrutiny. It is, however, quite obvious that no one single factor, with all allowance made for its quantitative variations, can possibly explain the protean forms of the disease tuberculosis. It is in the interaction of all factors that a valid explanation must be sought.

The first infection is in the vast majority by inhalation and the first focalization is in the pulmonary parenchyma. This first infection is with the extremely rare exceptions of transplacental inoculations acquired through outside sources, but the frequency of tuberculous disease throughout the population is still great enough that not by far all primary infections can be accounted for by a known source. The first infection causes two potentially permanent alterations in the host: it produces allergy and it establishes within the body a deposit of tubercle bacilli. In other words, from this event on the body is—probably for rest of its life—potentially exposed to two different sources of further infection: one within the body, making endogenous reinfection possible, the other the environment, which may cause an exogenous reinfection. That both mechanisms may occur is certain. Which mode of reinfection is predominant is one of the most vexing questions; it is the central problem in the pathogenesis of pulmonary tuberculosis in the adult and it is the all important question for the epidemiology of the disease. Since lately much emphasis has been laid on exogenous reinfection, it might not be amiss to stress here the endogenous mechanism, without the intention of belittling the potentialities of the former. The opinion that favors the more or less exclusive importance of exogenous reinfection is based essentially on statistical work, comparing contact and noncontact groups. However, the groups examined are usually slum populations. One may well question whether the insanitary living conditions per se are not a most significant condition to make reinfection, be it endogenous or exogenous possible. In other words, many persons may not and do not develop clinical disease though they are exposed to open tuberculosis, but, if the strain of slum conditions or intercurrent disease is brought to bear on the

individual, he may succumb to his endogenous or exogenous sources of infection. For all practical purposes the problem resolves itself into the question whether living conditions in the widest sense of the word or whether exposure to an exogenous source of infection is the dominant factor in producing postprimary disease. The mere fact that painstaking epidemiologic studies are necessary to prove the greater frequency of clinical disease in contact than in noncontact groups is a strong argument against the sovereign importance of exogenous reinfection. No such studies were necessary to establish the contagiousness in many diseases even before their etiologic agents were known. On the other hand, the reality of endogenous reinfection is proved beyond doubt by the frequent occurrence of foci in localizations that could not possibly be reached by direct exogenous reinfection, such as the skeletal system, the urogenital tract or the brain. It seems important to arrive at a proper balance between the two opinions, because it will determine the most successful method of case finding and appropriate measure in the prevention of the disease and it will guard against an alarmistic attitude that threatens to bring back the time when tuberculosis was treated in the pesthouse.

Most case finding work is now based on contact examinations, but nobody knows whether more clinical cases would be found among ten thousand contacts or among ten thousand persons living below a minimum subsistence level. The same may be said with regard to population groups according to age, race or occupation, although the enormous differences that exist in tuberculosis morbidity between the white and the Negro races, between adolescent girls and mature men, between low and high income groups, are roughly known. These differences become obscured by the emphasis on exogenous reinfection without being explained by it. Overemphasis on exogenous reinfection is apt to cause an underestimation of the constitutional and socio-economic factors that play an important role in endogenous infections and that are sometimes more easily remedied than exogenous sources of reinfection.

The school of thought that denies the possibility of exogenous reinfection leans heavily on the results of animal experiments. With an extremely careful—and one might say lucky—balance between dosage of first and secondary infection, and with optimal timing between the two infections, it can be shown that a practically complete immunity against exogenous reinfection may be developed in infected animals. But this is possible only in the exceptional experiment. In the natural course of events such optimal conditions do not occur in human life. The immunologic change that is brought about in man by a first infection is, as a rule, not manifested by a complete resistance to exogenous reinfection but by the much greater tendency in infected beings to a stricter localization of the lesion and by a greater tendency toward productive and fibrotic lesions.

Whether a lesion is productive or exudative depends, according to some authors, entirely on allergy. While the immediate allergic reaction is well known in its histologic manifestations, the fact that, more often than not, exudative and productive lesions are found in the same lung in close proximity shows at once that one single factor, such as allergy, is totally inadequate to explain the two essentially different tissue reactions. Again the many different factors that determine the

relation between parasite and host must be thought of. Exudative and proliferative tissue reactions are determined not by one condition, such as allergy or immunity, but by these conditions plus dosage of infection, plus constitutional characteristics, plus specific localization and so on ad infinitum. The essentials of practical importance that are known of allergy in tuberculosis can probably be expressed in two brief statements: 1 Allergy can be produced only by infection with (living or dead) tubercle bacilli. 2 Allergy accentuates and hastens the native tissue reactions against tubercle bacilli.

In corollary it should be said that neither exudative nor proliferative changes are in themselves malignant or benign. Either may heal or progress.

In the progression of tuberculous lesions is found probably the clearest expression of the differences between primary and secondary infections. The functional difference between the two is allergy, whether or not these differences indicate immunity in the reinfected person is not so much a matter of factual divergence of opinions as of arbitrary terminology. Pathogenically the differences are that in the progression of a primary lesion all available routes of propagation of bacilli come into play: lymphatics, blood stream, preformed channels, such as the bronchial tree, the intestinal canal, and the excretory ducts of the urogenital system. In secondary infections, dissemination through lymph and blood stream is quite infrequent, increasingly so with the increase of time elapsed between primary and secondary infection. Progression by continuity and through preformed channels continues unhindered in secondary infection. Thus as a characteristic example of progressive disease following more or less immediately primary infection is seen generalized miliary tuberculosis, frequent in childhood, rare in later life, and the characteristic progressive disease of adult life—tuberculosis limited to one organ system, such as pulmonary phthisis, rare in childhood, frequent afterward.

It remains now to describe briefly the most significant milestones of the morphologic aspects of pathogenesis. Be it said at the outset that an infinite variety of lesions occur, that only few can here be mentioned. But the few are chosen in such a way as to illustrate characteristic developments, so that practically all other lesions can be fitted somewhere in this general scheme, which in itself should provide a reasonably safe guide through the apparent maze of the disease tuberculosis.

The first focalization of bacilli occurs as a rule in the parenchyma of the subpleural layers of the lung, relatively rarely in the apex. The earliest lesion is a tuberculous pneumonia, which soon becomes surrounded by proliferative tissue changes from which a dense fibrotic capsule develops around the center, which in turn undergoes caseation and calcification. Simultaneously or somewhat later the mediastinal lymph nodes become involved through lymphatic transport of bacilli, they undergo rapid caseation and then show more or less completely the same retrogressive changes as does the parenchymal lesion. The most frequent development of this primary complex, consisting of parenchymal and lymphoglandular focus, is retrogression without clinical disease leaving the unmistakable pathologic marks of a well demarcated parenchymal calcified focus and frequently multiple, calcifications in the mediastinal lymph nodes. In this stage the tuberculous infection may remain and does remain in the majority

of all infected persons a scar, as it were, which with allergy caused by the infection is then the only mark left. In some cases the parenchymal focus may progress by contiguous spread, causing extensive caseous pneumonias and excavations.

More frequently the parenchymal focus heals while the lymphoglandular focus smolders on for greatly varying periods, discharging at intervals bacilli into the lymph and blood stream, they may focalize anywhere in the body, causing bone lesions, urogenital disease, scattered lobular pneumonic foci usually in the upper portions of the lungs, or, if a massive discharge of bacilli from a liquefied caseous lymph node occurs the result may be a generalized miliary tuberculosis. The borderline between the period of primary infection and that of those not infrequent early disseminations is too blurred to permit, as has been suggested, a strict differentiation into a primary and secondary stage, as in syphilis. Unlike untreated syphilis, the so-called secondary stage may never occur, or, again, it may manifest itself at any later stage of the disease. The foci created by early dissemination are, like any tuberculous lesion subject to the potential developments—progression or retrogression, and, histologically seen, they may caseate, liquefy and excavate or fibrose and not infrequently calcify or apparently completely resorb.

Pulmonary lesions similar to those seen during childhood in the phase of early dissemination are sometimes seen in adults. It is likely that the majority result from lymphohematogenous spread from primary lymph node foci. The pulmonary foci—true hematogenous tuberculosis—are symmetrically seeded throughout both lungs. Not infrequently they heal clinically by resorption, fibrosis or calcification, others excavate and then continue the usual course of bronchogenic phthisis.

Following the more or less complete healing of the primary complex or subsequent to major or lesser manifestations of early dissemination, a latent period usually intervenes before tuberculosis in the adult develops. In many cases of early dissemination, no further clinical manifestations occur.

The typical pulmonary tuberculosis of adult life begins in most cases with a single, initially exudative, focus. There are essentially three mechanisms by which this clinically primary focus may develop: 1 A bronchogenic spread occurs from incompletely healed apical lesions, the remnants of foci produced by early dissemination. 2 Bacilli from a still active primary lymph node focus are discharged into the lymph stream, are carried into the blood stream and are filtered out in the lung. 3 Bacilli are inhaled from the outside. Regardless of the mechanism by which the new focalization takes place, the early lesion is a tuberculous lobular pneumonia, which is seen most frequently in the subapical region. This lesion is always unstable, it soon progresses or retrogresses. Demonstrable involvement of the regional lymph nodes practically never occurs. This exudative focus, the so-called Assman focus, or early infiltrate, or infraclavicular infiltrate, again is subject to all the potential developments: resorption, fibrosis, caseation, liquefaction, excavation. If a cavity develops, a frank and perilous source of bacillary dissemination is established, from which at any time new bronchogenic spread may occur. From this point on, bacillary propagation through preformed channels and localized destructive lesions constitute the main character of the disease. Within the lung this means bronchogenic spread, and beyond its boundary it means ulcerative tuberculosis of larynx

and intestine. Every new focus is likely to start with a pneumonic lesion which is in no way different from the first early infiltrate, except that, owing to the potential massiveness of the bacterial invasion, it may be quite large and rapidly destructive. Progression and repair occur in succession or simultaneously, and the picture may further be complicated by hematogenous disseminations. The natural course of progressive pulmonary tuberculosis is, then, a series of bronchogenic tuberculous lobular pneumonias, which may heal or progress, fibrose or excavate, it is a series of pathologically acute phases of new focalizations and excavations, interrupted by periods of relative quiescence and partial repair. A patient with progressive pulmonary tuberculosis may finally die from progressive destruction of his pulmonary parenchyma, or, since repair is achieved principally by fibrosis, it becomes understandable that he may die eventually from the crippling tissue alterations that healing brings about.

Pathogenic considerations are incomplete without a discussion of the potentialities of healing. Part of this has already been mentioned. In brief summary, tuberculosis may heal spontaneously at almost any phase of its development, the exceptions are (1) massive blood stream infections, (2) focalization in vital regions (e.g., the fourth ventricle) and (3) large excavations with hard, fibrosed walls. In order of frequency, spontaneous healing takes place (1) in the primary complex, (2) in mild early dissemination, (3) in the early infiltrate. Once a cavity has developed, with its imminent danger of bronchogenic dissemination and hemoptysis, the chances of spontaneous healing are much lessened and they decrease progressively with the hardening of the cavity walls and with the involvement of more tissue. Since all therapeutic measures in pulmonary tuberculosis, including collapse therapy, are directed toward establishing conditions more favorable to natural healing mechanisms, the foregoing remarks on spontaneous healing apply equally to healing under any form of rational therapy.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. MILLER AND RAFFAPORT
AND DR. PINNER

DR. HENRY C. SWEANY, Chicago. This complex subject has been covered by Dr. Pinner in the fewest possible words. The first infection usually begins in the lung as a rather sluggish or subacute pneumonic process and is made up of a definite cytologic picture of monocytes, lymphocytes entwined in fibrin, with a few polymorphonuclears scattered about and an occasional Langhans giant cell. The area may be from a secondary lobule to a whole lung in size or there may be multiple foci. From this onset there is a gradual change throughout life, consisting of fibrous encapsulation, central caseation, calcification, resorption and ossification. Subsequent to the local lung lesion, there is that characteristic, inherent in all infections to progress by the lymphatics. This progression goes toward the blood stream and affects the lymph nodes in a similar manner to the lung lesion, but it may vary quantitatively. It usually progresses onward spilling over into the blood stream, causing a variable degree of dissemination into the lesser circulation and even on through the lungs again into the general circulation, localizing in distant organs. This lung and lymph node phase described first by Parrot was crystallized by Ranke into what he chose to call the first stage of the primary complex. The spilling into the blood stream was the second stage and the organ localization the third. Rightly or wrongly he had a stage of allergy for each. The problem of allergy however is surely not so simple, as there is the complex problem of immunity involved. As the lesion ages it may either heal or spread and in either case there result varying degrees of cal-

cification, which were well described twenty years ago by Ghon and have since been known as Ghon foci. These primary lesions may vary with the type, dosage and virulence of the bacilli and with the constitution, race and especially the age of the host. A small pocket of bacilli may gain a special virulence in one lesion and not in another. A small or moderate sized dose with allergy may be overcome as a result of the allergy, but a large dose usually results in violently exudative lesions. Adult primary lesions tend to be more localized in the lung and are not so prone to calcify as those of children. Aboriginal races usually react more like children to primary tuberculosis. The sequela of healed phthisis is frequently an emphysema that varies in extent and degree as the original area of disease. Sometimes this emphysema incapacitates so much lung that the right side of the heart is embarrassed beyond recovery. Other late sequelae are bronchiectasis, abscess, atelectasis and distortion of bronchi and blood vessels, which cause variable degrees of distress.

DR. F. M. POTTENGER SR., Monrovia, Calif. When the tubercle bacillus was accepted as the cause of tuberculosis the previously held idea of heredity was thrown away and it was thrown too far away. At the present there exists a leaning again toward the importance of heredity. Variations are seen in the reaction of individuals toward tubercle bacilli that can best be accounted for by differences in the patient's tissues. I like to think of the whole question of tuberculosis—infection, diagnosis and therapy—as being related to the body's physiologic reaction. When the numbers of bacilli are too small to produce infection, the normal physiologic response is able to destroy them. When the numbers are greater or more virulent, the reaction is still physiologic, but it is a quickened and heightened response. There is an attempt on the part of certain individuals to separate allergy from other phases of immunologic response. This, to my mind, proves to be confusing. Allergy is an intracellular reaction, physiologic in nature, by which the body acts quickly and energetically in destroying bacillary protein. It is only one part of the general physiologic response of the body toward infection, but it cannot be separated from the inhibiting influence on the growth and development of bacilli, the increased phagocytosis that is shown by the mononuclears, the development of the tubercle, or the increased permeability of the vascular bed surrounding the tubercle. They are all a part of the defensive mechanism. Certain research work of F. M. Pottenger Jr. bears on the body's physiologic response to tubercle bacilli. In the past three years he has been able to protect 30 per cent of three different groups of guinea pigs from infection from virulent bacilli by treating them with adrenal cortex extract, and in the treatment of asthmatic children he had found seven to react at the beginning of treatment to No. 1 purified protein derivative tuberculin but who after from six to twelve months treatment, have lost their cellular reaction and fail to respond to No. 2 purified protein derivative tuberculin. I do not know just what this means, but it is in line with known knowledge that the medullary substance of the adrenal gland has an important factor in preventing anaphylactic and allergic reaction. The cortical portion acts synergistically with the medullary portion, and so by its use he has been able to protect against infection and also to change the cells of the body so that they no longer react with inflammation when tuberculin is brought in contact with them. I look on this as a method of increasing the patient's normal physiologic reaction and making it possible for him to care for more bacillary protein without inflammatory response.

DR. JAMES ALEXANDER MILLER, New York. We have listened today, in Dr. Pinner's very brief and concise exposition of the pathogenesis of tuberculosis and in Dr. Sweany's discussion to a very illuminating discussion of the basis on which we as clinicians must erect our structure of the understanding of and the treatment of this disease. I know that in my own particular case it has been true that my whole interpretation of the disease rests on the pathogenesis.

DR. MAX PINNER, Oneonta, N. Y. I was pleased that Dr. Sweany emphasized progressive types of first infections, particularly since in recent years the so-called childhood type of infection has been frequently considered to be invariably benign. I do not know how this concept has originated but it certainly is not borne out by facts.

INTRAVENOUS TREATMENT OF MENINGOCOCCIC MENINGITIS WITH MENINGOCOCCUS ANTITOXIN

ARCHIBALD L. HOYNE, MD

CHICAGO

It is necessary to scan the official statistics of a city or state in order to realize fully the high fatality rates that have usually prevailed for meningococcic meningitis. In Chicago, from 1916 to 1933, the fatality rate for this disease has exceeded 40 per cent in every year but one. This was in 1921, when the rate was 39.2 per cent. In 1925 and 1926 the fatality rates were 72 per cent and 65.9 per cent respectively. From 1916 to 1935 inclusive the total number of reported cases in Chicago was 4,028 and the average yearly fatality rate was 47.7 per cent. During the Detroit¹ epidemic of 1928 to 1931 there were 1,686 cases, with a fatality rate of 50.5 per cent. Tripoli² reported a rate of 65.15 per cent for patients treated in New Orleans in the years 1925-1934. In chart 2 is illustrated the expected and actual fatality rate per hundred cases for the years 1926-1935 in Chicago.

At the Cook County Hospital in Chicago, during a period of nineteen years prior to 1934, the fatality rate for meningococcic meningitis has varied from 35 to 90 per cent.³ In those years all patients received serum intraspinally. At times, intracisternal, intraventricular, intravenous, intramuscular and intraperitoneal injections were resorted to, but only as auxiliary

Chart 1—Fatality rate per hundred cases of epidemic meningitis in Chicago from 1916 to 1935

measures. Failures in treatment were frequently attributed to lack of agglutinins in the serum or to unusual virulence of the infecting organism. Although intraspinal therapy has been regarded as a necessity from the time the serum was introduced, response to this mode of treatment often has been most disappointing. The fatality rates mentioned are in accord with this feeling.

When evaluating fatality figures for meningococcic meningitis, certain factors should be given careful consideration. Age has quite as distinct a bearing on prognosis as the virulence of the infecting organism. This fact is disclosed in table 1.

All the patients represented in table 1 received Ferry's antitoxin⁴ both intraspinally and intravenously. The fatality rate of 27.3 per cent for these 201 patients was regarded as very satisfactory. But it may be noted that for sixty-two patients who were 10 years of age or less the fatality rate was but 12.9 per cent. On the other hand, for eighty-three patients above the age of 20 the fatality rate was 45.7 per cent.

Is it proper to refer to the disease called meningococcic meningitis as an acute infectious disease of the central nervous system? Is there not justification in regarding the meningitis as a complication of an acute systemic infection? Such an interpretation is not far different from that which is now commonly placed on

Chart 2—Expected and actual fatality rate per hundred cases of epidemic meningitis in Chicago based on ten year moving average (1926-1935). Solid line, actual fatality; broken line, expected fatality.

poliomyelitis—a disease in which “paralysis may occur, but not usually.” As an inclusive term for all classes of meningococcic infection, the word “meningococcia”⁵ has been suggested. Meningococcic nasopharyngitis, meningococcemia without evidence of meningitis, meningococcemia with meningitis, and meningococcus carriers would all be embraced by the one name indicative of meningococcic infection. This classification assumes that when meningitis develops it is secondary to a blood stream infection. Herrick⁶ expressed such an opinion nearly twenty years ago in regard to the mode of travel of the meningococcus in the body. It is largely on the same theory that my associates and I have abandoned intrathecal therapy and concentrated our attention on the toxicity of the disease.

Our present procedure of treating patients for meningococcic infections is as follows. Immediately on admission to the hospital a sample of blood is obtained for culture. If the patient has petechiae, the blood culture is nearly always positive. Should there be little or no rigidity of the neck, a lumbar puncture need not be done at this time. Preparations are then made for intravenous therapy. Later, if the blood culture is negative, at least one spinal puncture is performed for the purpose of confirming clinical diagnosis.

It should be stated at this point that antimeningococcus serum or meningococcus antitoxin has been given to alternate patients in order to compare therapeutic effects. This was done irrespective of the age, day of disease, or condition of the patient. Whether meningococcus antitoxin or antimeningococcus serum is to be injected, it is given diluted in 10 per cent dextrose in physiologic solution of sodium chloride of at least twice the volume of the therapeutic agent. From 5 to 15 minims (0.3 to 0.9 cc) of epinephrine is added to the mixture. It is then administered by the gravity method at body temperature. The flow should approximate about 60 drops per minute. If difficulty is encountered in inserting the needle, venesection is always justifiable. Any suitable vein in an extremity

may be selected. Whether the arm or leg is chosen, the part should be immobilized on a splint. It is unnecessary to state that aseptic methods should be adhered to.

When meningococcus antitoxin is used the initial dose is usually from 50,000 to 100,000 units. The smaller dose may suffice for a child, the larger one for an adult. Thirty cubic centimeters of the unconcentrated antitoxin contains 10,000 units, therefore, by volume the quantity will be 150 cc for 50,000 units, or 300 cc for 100,000 units. If one of the standard antimeningococcus serums is selected, the dose is generally from 150 cc for a child to 200 or 300 cc for an adult. In either instance antitoxin or serum may be repeated at twenty-four hour intervals if it seems indicated. Frequently only one large dose of antitoxin or serum will be required. However, very recently we administered 100,000 units of antitoxin intravenously on four consecutive days. The patient was a woman who had been ill for six days prior to admission to the hospital. She entered in coma and continued in this state for three days after admission. She made a complete recovery without complications and was discharged after being in the hospital for twelve days.

Nearly all patients receiving intravenous therapy develop urticaria from five to seven days later. Seldom, however, are there any serious reactions. When the therapeutic agent is diluted as described, reactions are no more severe than when undiluted serum is injected intraspinally.

In table 2 are shown the results secured in the treatment of sixty-six meningococcic patients without resort to intrathecal therapy. In these cases the clinical diagnosis was confirmed by blood culture or spinal fluid examination in all but four instances. The patients were treated during the years 1934, 1935 and 1936 and constitute all patients so treated in the contagious disease department of the Cook County Hospital during those years up to April 11, 1936. Since January 1 of this year, no meningococcic patient admitted to either the Cook County Hospital or the Municipal Contagious Disease Hospital has received any intraspinal therapy. At the Municipal Contagious Disease Hospital, thirty patients have been treated in this man-

patients was 14.2 per cent. This wide difference in apparent therapeutic efficiency between the antitoxin and serum groups is not usually so marked.

Additional figures illustrative of our results in the treatment of meningococcic meningitis without intraspinal therapy at the Cook County Hospital during the present year are as follows:

From Jan. 1 to April 11, 1936, fifty-two patients were admitted. Among these the fatality rate was 19.2 per cent. The average number of days of illness

TABLE 2—*Meningococcic Meningitis Treated Without Intraspinal Therapy at the Cook County Hospital Contagious Disease Department*

| Age | Sex | | Total | Anti-toxin | Serum | Recovered | Died | Fatality per Cent |
|---------|------|--------|-------|------------|-------|-----------|------|-------------------|
| | Male | Female | | | | | | |
| Under 1 | 2 | 0 | 2 | 1 | 1 | 2 | 0 | 0 |
| 1-5 | 7 | 8 | 15 | 12 | 3 | 15 | 0 | 0 |
| 6-10 | 6 | 1 | 7 | 5 | 2 | 7 | 0 | 0 |
| 11-15 | 6 | 7 | 13 | 5 | 8 | 12 | 1* | 7.6 |
| 16-20 | 4 | 2 | 6 | 3 | 3 | 6 | 0 | 0 |
| 21-30 | 12 | 2 | 14 | 3 | 11 | 12 | 2† | 14.2 |
| 31-40 | 4 | 1 | 5 | 2 | 3 | 3 | 2† | 40.0 |
| 41-50 | 0 | 3 | 3 | 0 | 3 | 2 | 1* | 33.3 |
| 51-65 | 0 | 1 | 1 | 0 | 1 | 0 | 1* | 100.0 |
| Total | 41 | 21 | 66 | 31 | 35 | 69 | 7 | 11.8 |

For forty-three patients 20 years of age and less the fatality rate was 2.3 per cent.

For thirty-one antitoxin-treated patients the fatality rate was 6.4 per cent.

For thirty-five serum-treated patients the fatality rate was 14.2 per cent.

* Serum-treated patient.

† One patient was treated with antitoxin and one was treated with serum.

on admission for this group was 3.8. The average number of lumbar punctures for forty-two recovered patients was 2.1. The average dose of antitoxin per patient was 221,000 units, and the average dose of antimeningococcus serum was 363 cc. The number of hospital days averaged 14.5 for the antitoxin group and 15.3 for serum-treated patients.

The number of meningococcic patients treated exclusively by the intravenous route at the hospitals named was ninety-six. The fatality rate for the combined groups was 15.9 per cent.

When serum or antitoxin is administered in adequate dosage intravenously there is usually a marked decline in temperature, which may reach normal within twelve hours. If satisfactory response to the initial dose of antitoxin or serum is not apparent within twenty-four hours, the dose is repeated. Frequently in severe cases a second dose of antitoxin or serum is administered twelve hours following the first. If there are evidences of intracranial pressure two or three days after the beginning of treatment, a second lumbar puncture may be made. When this is done a pronounced decline in the cell count of the spinal fluid is usually noted. Often, too, a smear and culture of the spinal fluid will show the absence of organisms. This seems surprising when one considers the long accepted opinion⁷ in regard to the necessity for bringing the specific serum into direct contact with the meningococci. During the past year we have frequently observed that patients with high spinal fluid cell counts and positive cultures for meningococci at the time of first antitoxin or serum administration intravenously will have low cell counts and sterile spinal fluids two or three days later. In some

TABLE 1—*Antitoxin Treated Cases According to Ten Year Age Groups*

| Grand totals | | | | 201 | 33 | 27.2 | |

ner between January 1 and April 11, 1936. For the latter group the fatality rate was 20 per cent.

In table 2 it will be noted that the fatality rate for all cases was only 11.8 per cent. What is still more significant is the fact that for the forty-three patients who were 20 years old or less, the fatality rate was only 2.3 per cent. For the thirty-one antitoxin-treated patients irrespective of age the fatality rate was 6.4 per cent. The fatality rate for all serum-treated

⁷ Zinsser, Hans. *Resistance to Infection*. Little, Brown, New York, Macmillan Company, 1931, p. 19.

instances only a single lumbar puncture has been made, and even though meningococci were found on smear and culture no subsequent puncture was done. Such patients have made excellent recoveries without complications. The period of their hospitalization has been brief. In many cases it has been extended beyond the requirements of the patient merely for the purpose of complying with quarantine regulations. In Illinois the minimum quarantine is fourteen days from the onset.

As further evidence that intrathecal administration of an antiserum is not necessary in the treatment of meningococcic meningitis, attention is directed to table 3. Here nine patients are represented. No puncture was made on any one of these patients. The ages varied from 8 months to 6 years. All had petechiae. In each instance the blood culture was positive for meningococci. There was very little rigidity of the neck in most of the members of this group. In some cases the temperature was between 105 and 106 F when intravenous treatment was started. One child was in coma and cyanotic when admitted to the hospital, he stopped breathing in the receiving room and was given artificial

respiration. During the administration of 100,000 units of meningococcus antitoxin intravenously, his color returned to normal. Twelve hours later his temperature was approximately normal and he was mentally alert. His recovery was complete five days after admission, except for a serum rash that developed on his seventh hospital day.

Most of the fatal cases at the Cook County Hospital among those treated by the intravenous method exclusively occurred among patients who were extremely bad risks. For example an alcoholic patient, aged 39, a woman, aged 64, a patient with aortitis, and one with multiple fibroids and other pathologic conditions of the abdomen.

On several occasions, patients with meningococcic meningitis who appeared to be suffering from an overwhelming toxemia responded slowly to intravenous treatment. Usually these were patients who had been ill for a number of days before hospitalization. They assumed the picture of an encephalitis as the spinal fluid approached normal. Several patients of this character eventually made complete recoveries and have remained well after discharge from the hospital. In a few instances death occurred after the spinal fluid had been found negative for organisms by culture. Autopsies in these cases showed no evidence of meningitis but did disclose the presence of encephalitis which we

ascribed to the toxic action of the meningococcus. There was no pus in the ventricles, though in one case the ventricles appeared dilated, an internal hydrocephalus had probably developed. These changes seem to uphold still further the important part played by the toxic action of the meningococci.

When meningococcic meningitis patients are treated by the intraspinal route, opisthotonos is common. Increased irritation of the meninges is undoubtedly caused by the introduction of a foreign substance into the intrathecal sac. If this form of treatment is adopted early in the septicemic stage, meningitic signs almost invariably become more pronounced. As a matter of fact, it seems to me that meningitis may be induced when there was formerly no evidence of its presence. On more occasions than one, we have found that examination of spinal fluid withdrawn early in an attack of a meningococcic infection did not reveal the presence of meningococci, nor did a high cell count exist. In view of these facts, should we not devote more attention to the systemic infection and think less of the organisms? Too often the toxic action of the meningococci is ignored while intraspinal therapy is being carried out. Moreover, with intraspinal therapy, problems relating to blockage are sometimes encountered. Secondary infections are also a possibility which cannot be totally overlooked. The frequent subjection of the patient to discomfort, pain and perhaps permanent injury of the vertebral column as the result of numerous spinal taps is a further objection to frequent lumbar punctures.

Suppurative processes are seldom encountered when the patient is treated by the intravenous method exclusively. Panophthalmitis is one of the most serious complications of epidemic meningitis. This complication has not occurred in any patient receiving exclusively intravenous therapy. Endophthalmitis, iridocyclitis and optic atrophy have occurred, but neither eye nor ear complications have developed in any antitoxin-treated patient after this form of therapy has been instituted. The few eye and ear complications that developed in serum-treated patients we attributed to toxic rather than to suppurative influences.

Strabismus is not an uncommon complication early in the attack of meningococcic meningitis, although the condition usually improves during the course of treatment. Facial paralysis and even complete hemiplegia at the time of hospitalization have recently been noted among our patients. These cases happened to be antitoxin treated and recovered completely. Hydrocephalus is very common among infants when treated by intrathecal injections of serum. With exclusive intravenous therapy it is encountered much less often. The old theory that frequent lumbar punctures are necessary to prevent hydrocephalus seems doomed to the discard on the basis of our recent experiences. In fact, it seems to me that numerous punctures serve to induce a greater secretion of spinal fluid. Hypertonic solutions such as sucrose intravenously are often of value.

Thus far we have had no discharged patients who were treated exclusively by the intravenous method reenter the hospital because of recurrences. In the past, when patients were treated intraspinally, this was not an extremely rare happening.

COMMENT

1 The fatality rate for meningococcic meningitis at the Cook County Hospital during nineteen years prior to 1934 varied from 35 to 90.4 per cent. The average was 50.6 per cent.

2 Meningococcic meningitis is interpreted as a blood stream infection with accompanying toxemia. Meningitis is regarded as a complication.

3 The intrathecal method of therapy prolongs recovery of the patient.

4 Massive doses of the therapeutic agent intravenously are advised.

5 For sixty-six patients who received only intravenous treatment the fatality rate was 11.8 per cent. For forty-three of these patients who were 20 years of age and less the fatality rate was 2.3 per cent.

6 A total of ninety-six patients were treated exclusively by the intravenous route, with a fatality of 15.9 per cent.

7 Of nine meningococcic patients treated intravenously without any lumbar puncture, only one died.

8 Supportive complications were not encountered with intravenous therapy. Fewer complications occurred with Ferry's meningococcus antitoxin than with antimeningococcus serum.

3026 South California Avenue

ABSTRACT OF DISCUSSION

DR ALBERT G BOWER, Hollywood, Calif. Dr Hoyne reports forty-three cases under the age of 20 years treated entirely by massive intravenous doses of antitoxin. His fatality rate was only 2.3 per cent. It has long been noted that the younger age groups show the greatest response to therapy, with the lowest death rate, but a rate as low as this is almost unbelievable in the light of past experience. The reason for a lower death rate in younger children is difficult to explain in view of the work of Silverthorne and Fraser on the action of human blood on the meningococcus. They showed that the blood of most adults is bactericidal to a high degree, whereas children and infants possess little or no bactericidal property in their blood. Does this mean that those adults who acquire epidemic meningitis represent a particularly susceptible, nonreacting class with regard to therapy? The data regarding the shortening of the duration of the disease, the stay in the hospital and the lessening of complications are likewise most significant. It must be remembered, however, that when meningitis and its treatment are discussed the disease as it is known in one's own particular geographic location is being discussed. Nearly all investigators have long held that the meningococcus and its products exercise a selective affinity for the cerebrospinal system and that with the exception of the hematogenous type its appearance in the blood stream has been quite transient. If this is so a humoral immunity must develop quite rapidly and be reflected in the circulating blood stream. Yet it does not get through the choroid plexus to reflect its antimeningococcic effect in the spinal fluid, for these patients do not get well until additional serum treatment is instituted. I am convinced that in at least some cases this must be true. For since January I have successfully treated four cases with the patient's own serum administered intrathecally, after the intraspinal administration of commercial antimeningococcus serum failed to effect a cure. All patients lived when their own blood serum was given by spinal puncture. Mehrrens work showing that in 20 per cent substances introduced into the blood stream do not get over into the spinal fluid tends to afford strong support to this view. When antimeningococcus serum is to be used instead of antitoxin, the best clinical results will be obtained by selecting that serum which agglutinates most rapidly and in the highest titers the organism cultured from the individual patient.

DR GERALD F KEMPF, Indianapolis. Dr Hoyne is to be commended for his courage in introducing the use of intravenous therapy alone. However, most of us would agree that in those cases which do not exhibit marked evidence of toxemia and bacteremia one probably should adhere, at least in some measure to intraspinal therapy. His results both with the antitoxin and with the antiserum appear to speak for them-

selves. However, since the question of antiserum against antitoxin has been raised I should like to say that last year my associates and I treated seven cases of meningococcic meningitis with antitoxin intrathecally and intravenously and lost the seven cases. At the same time we treated ten cases with antiserum and lost four. Conclusions cannot be drawn from such a small group because I have seen as many as seven patients with meningococcic meningitis come into the hospital on the same day and all die within forty-eight hours. I should like to ask Dr Hoyne whether, in his comparison, the 120,000 units of antitoxin in one group as against 271 cc. of unconcentrated antiserum in the other group is not actually 360 cc. of horse serum, in other words, the antitoxin treated group was getting 25 per cent more serum than the antiserum treated group. This may account for the small differences in mortality and morbidity.

DR GILBERT J LEVI, Memphis, Tenn. It has occurred to me that in two diseases strikingly different methods of treatment have recently been employed. (1) In tetanus the recent teaching is that treatment by the intravenous and intramuscular routes is to be preferred to the time honored treatment, that of spinal puncture and spinal therapeutics, (2) now the pendulum has swung in the case of meningococcic meningitis. It was formerly taught by Dr Flexner that serum therapy by the spinal route was the ideal method and his results were strikingly good. Later, during the World War, Dr Herrick urged large intravenous doses of the serum. This, too, combined with intraspinal therapy, proved effective. However, Dr Hoyne's results are the best to the present time. Dr Hoyne advocates the treatment by vein alone. My associates and I have attempted the use of the antitoxin during the past three years. In a series of over 200 cases our mortality was about 35 per cent. I must admit, however, that our intravenous medication has not been in the amounts advocated by Dr Hoyne. This we intend to do. The death rate in our community has been parallel with that in Chicago. Our mortality average for a period of sixteen years has been about 50 per cent. However, during the past two and one-half years, with the use of the new antitoxin given both intrathecally and intravenously, the mortality has been reduced to 35 per cent. I should like to ask Dr Hoyne whether it would be possible in the interest of economy to concentrate the antitoxin so as to make a smaller but a more highly concentrated dose.

DR ARCHIBALD L HOYNE, Chicago. There are great variations in the fatality rates of meningococcic meningitis in different sections of the country, and also in different years. We are comparing our present rates at the County Hospital with the years gone by, and while it is true that the fatality rate may rise again, the point is that at present it has never been so low, and therefore we think the treatment has a great deal to do with it. We have considered convalescent serum but have not administered it in the manner suggested by Dr Bower. The idea of adding complement may be of great assistance, and perhaps in the future it will improve matters still more. The question of the permeability of the meninges is one that is often discussed. Exactly what happens may not be known but it is a fact that introduction of the serum in large quantities into the blood stream results in organisms disappearing from the spinal fluid. It is possible that, in the future, intraspinal therapy may be resumed. Our present results make it appear doubtful. In answer to Dr Levi's question I think that if the serum should be concentrated it would be of great help. With Ferry's antitoxin we have not been concerned so much with the types of organisms as with the toxemia. Little attention has been paid to the power of the various standard serums to agglutinate. A few years ago in Chicago, I followed cases in which serum was used and found that in many instances the best results were obtained with serums that did not agglutinate very well. It would be a great help to have the antitoxin concentrated. At present 100,000 units of antitoxin means 300 cc. of serum. In other words in 30 cc. of unconcentrated antitoxin there is only 10,000 units. A small amount of the concentrated antitoxin was made up in which 10 cc. contained 20,000 units. We have lost far fewer eyes and had very much less deafness with the use of the Ferry preparation than we have had with any of the standard serums.

OSTEOMYELITIS OF THE INFERIOR SURFACE OF THE PETROUS PYRAMID

WELLS P. EAGLETON, MD
NEWARK, N. J.

Our knowledge of infections of the petrous apex is still very primitive, it is in the same condition that mastoid infection was forty years, and Bright's disease one hundred years, ago for, like mastoiditis and Bright's disease apicitis is a generic term, covering a large number of different pathologic states, the symptoms of which are modified by the surrounding parts.

Because of the peculiar nature of the bone, the pathologic process in the vast majority of cases has a tendency to (a) spontaneous cure—while about 15 per cent end in (b) abscess formation, many of which today are saved by well directed treatment, while a very few, I think about 5 per cent, continue throughout as (c) invasive forms of thrombophlebitis and are uniformly fatal.

The differentiation of the exact pathologic lesion present is of the highest surgical importance, as any ill directed surgery on the delicate endothelial blood vessels making up the sinusoidal spaces of the apex, which are the site of suppuration, only too frequently precipitates the very lesion that one is attempting to prevent, converting a local sinusoidal osteomyelitis into an invasive infection of the blood vessels, which rapidly spreads into the vessels of the meninges and cerebral tissues, causing either a fulminating meningitis or an infective meningo-encephalitis.

Thus each variety of petro-apicitis requires clinical differentiation because the specific line of treatment to be adopted depends not only on the nature of this lesion but on its anatomic position in the bone, if one is to prevent the development of a complicating, generalized septic meningitis, which is the cause of practically all fatalities from apical infections. For surgery in apical infections must have for its immediate and ultimate aim the prevention of a meningitis, or its cure if present at the time.

The petrous apex, from a pathologic and surgical standpoint, is divisible into three domains.

First the marrow-filled osseous matrix itself, with its dural coverings on its anterior and posterior surfaces. The red bone marrow after the completion of bony growth may become converted into pneumatized cells, which pneumatized bone, if infected, becomes the seat of (1) a sclerosing or a suppurative type of osteitis. If, however, an apex continues to contain acellular fat marrow, which is potentially capable of becoming cellular red bone marrow, possessing active immunizing properties against infection, the lesion in the apex brings (2) a reparative type of osteomyelitis—a plasma cell formation which also usually ends in a secondary osseous sclerosis. However, when the protective reaction in the marrow is overpowered by bacterial invasion it becomes the seat of one of the numerous types of infective osteomyelitis (a) phlegmonous, (b) suppurative with the formation of pus (abscess of the apex), or (c) chronic cariogranulomatous osteomyelitis.

Second the domain of the carotid canal which, passing through the petrous apex, contains the carotid artery surrounded by its carotid venous plexus. Thrombo-

phlebitis of the carotid plexus may give rise to (1) a local extradural abscess on the superior surface of the apex over the carotid artery, as the vessels here lose the bony covering. But phlebitis of the carotid plexus much more frequently causes (2) cavernous sinus thrombophlebitis or (3) an invasive form of thrombophlebitis of the small vein, the latter only too often giving rise to (4) a pial vein meningitis.

Third, the inferior "cribriform" perforated plate on the pharyngeal surface of the apex. Infection here causes (1) a localized abscess of the lateral pharyngeal roof. The suppuration in its effort to discharge externally may invade the soft parts of the lateral wall of the nasopharynx. Some cases of low grade infection take on (2) an invasive osteomyelitic caries of the base of the skull, which, extending great distances, forms multiple fistulas in the throat and neck. The infective process in the bone has a tendency to occasion a retrograde thrombophlebitis in any vessel that it encounters generally terminating in death from meningitis and venous sepsis.

THE TWO SURGICAL LESIONS OF APICAL INFECTION ABSCESS AND SMALL VEIN PHLEBITIS

Thus it may be stated that surgery of the apex resolves itself into two distinct lesions, namely, abscess formation, which requires evacuation, and infective thrombophlebitis of small vessels, which requires rest and patient watching until it in time either undergoes resolution or breaks down into pus, when that pus must be evacuated, but it must be evacuated at the point farthest away from any inflamed vessels that enter the dura. If quiescent infected vessels that pass through the dura into the meninges are surgically injured, meningitis is apt to result.

FISTULOUS TRACTS INTO THE APEX

It is now well recognized that if a fistula can be found anywhere in the domain of the tympanomastoid, whether it is in (a) the retrofacial area, (b) the peritubal area or (c) the angle of the petrosal, it leads into the part of the apex that is diseased, and the enlargement of the fistula furnishes adequate drainage.

FISTULAS POINTING TOWARD THE LATERO- PHARYNGEAL ROOF

My experience teaches that such a fistula should uniformly be sought in the lateral pharyngeal roof, as the pus from an osteomyelitic area of the apex situated below the transverse portion of the carotid artery and in the bend that it makes before entering the cranial cavity has a tendency to point downward into the latero-pharyngeal roof. And in such a case the base of the apex and the domain of its adjacent sphenoid occipital articulation should be surgically exposed and explored.

THE CRIBRIFORM PLATE ON THE PHARYNGEAL SURFACE OF THE APEX

An examination of the inferior basilar surface of the bony petrous apex reveals an area mesial to the fossa cochlearis and carotid orifice and below the transverse portion of the carotid canal, which is studded by many small openings. This plate I would designate the "petrous cribriform," because of its resemblance to the cribriform plate of the infant's mastoid, which during growth develops into the surgically important landmark Macewen's triangle.

Through the openings of the petrous cribriform plate pass numerous vessels from and into the tissues of the lateral pharyngeal and prevertebral spaces. These

small vessels are numerous during infancy and early childhood, that is, while the cranial basis is growing, becoming obliterated after maturity, although throughout life they remain potential pathways by which infection that originates within the apex may escape into the throat or from the throat may pass into the bone.

The petrous cribriform plate varies greatly in size in different bones, depending on the size of the foramen lacerum, it is set deep in the base of the skull, looking downward and slightly backward.

An abscess originating in the medullary substance of the cribriform plate generally points into the vaults of the pharynx behind and slightly mesial to the eustachian tube and may extend above and posterior to the tonsillar fossa, sometimes causing the supratonsillar region to project slightly forward.

A TRUE OSTEOMYELITIC MASTOIDITIS COMMON IN INFANTS AND CHILDREN BEFORE THE THIRD YEAR

Mastoiditis of infants runs a course which is characteristic of true suppurative osteomyelitis, for it is a blood space pathologic process that is, suppuration within bone marrow spaces. This is why the mastoiditis of infants may give rise to toxic symptoms, diarrhea, and the like, which do not occur in infection which is confined to suppuration of pneumatic bone.¹ However, after the third year of life no trace of fat marrow is to be found within the domain of the mastoid apophysis² as mastoiditis after the second year is generally a local osteitis.

In infants and young children an infection from an apex is carried by lymph vessels, which causes the glandular enlargements and the lateral pharyngeal abscess, so frequently complications of otitis media of infants.

Later in life abscess of the lateral pharyngeal wall is not accompanied by a swelling of the cervical lymph nodes, the latter having undergone atrophy, since the protective mechanism of the throat passes from the lymphatic system into the compact bone protecting barrier with its covering of ever moving ciliated and glandular mucosa.

OTORRHEA AND LATERAL PHARYNGEAL ABSCESS IN THE VERY YOUNG

In the lateral pharyngeal abscess for a suppurating otitis of infancy, an operation on the antromastoid reveals little or no pus in the bone, but the bone spaces are filled with granulations,³ which is the bone marrow's method of control of infection.

Osteomyelitis of the petrous apex with retropharyngeal abscess may be a Brodie abscess. The disease is directly below the periosteum, not involving the medulla extensively.

CAUSE OF FAILURE IN DIAGNOSIS OF APICAL SUPPURATION IN INFANTS

The presence of (a) enlarged lymphatic glands in the neck, with the absence of (b) obstructed breathing without any (c) mastoid redness or tenderness has

frequently caused the osteomyelitic nature of the aural suppuration to escape recognition. The lateral pharyngeal abscess may be overlooked for a considerable period.⁴

History—H. C., a boy, aged 14 months, seen with Drs. L. A. Peer and H. Jackson had had tonsillitis two and one-half months previously. Some weeks later he had a "cold," with an up and down septic temperature, associated with swelling of the glands of the neck. On the second day of the cold a paracentesis of the left ear was performed, the ear discharged freely. The following day the right ear was opened, but there was no discharge from it until several days later, when it discharged, spontaneously.

For three weeks prior to admission the child continued to have a septic temperature, ranging from 98.4 to 103 F, with a discharge from the ears.

Examination—On admission to the Newark Eye and Ear Infirmary there was no mastoid tenderness but a swelling was to be felt in the right lateropharyngeal region, which, however, apparently caused no difficulty in swallowing or breathing. The swelling of the glands in the neck extended to the mastoid tip. The right fundus showed a blurring of the disk. Blood culture showed streptococcus.

Roentgenograms furnished evidence of mastoiditis of both sides, for, although there were no definite areas of necrosis, the trabeculae were hazy in outline and there was a slight increase in density in the right mastoid near the tip.

Operation—Double simple mastoidectomy was performed. The right mastoid was filled with granulations. The left mastoid contained granulations and a little pus.

The lateral pharyngeal abscess was opened and a large quantity of pus was evacuated. Culture from the left mastoid showed *Streptococcus nonhaemolyticus*.

Prompt recovery followed.

The infrequent occurrence of petro-apical abscess is evidence of the active protective properties of its marrow against infection in contrast to the frequency of suppuration in the pneumatic bone of the mastoid process.

Suppuration of the mastoid very frequently follows otitis, on the other hand, a purulent collection of pus in the petrous apex occurs but rarely, although roentgenograms of the apex will demonstrate that it is very often the seat of an infection in cases of suppurative mastoiditis which present no apical symptoms.

Osteomyelitis of the apex with little or no otitis does occur especially while the apices are growing, post-mortem examinations of infants and children reveal changes in the medullary substance of the apex and of the adjacent sphenoid basis without any evidence of an associated or of a preceding otitis.⁵ One of my autopsies revealed little disease in the mastotympanic region, although there was extensive destruction of both apices.

FISTULAS THAT POINT AND DRAIN INTO THE LATEROPHARYNGEAL ROOF

My attention was called to the tendency of the pus from an osteomyelitic area to point into the throat by the discovery post mortem of an abscess of the apex which was extradural and confined entirely to the posterior fossa, with bony caries involving the posterior surface of the apex and extending into the outer half

5 This personal observation has been confirmed by Dr. J. Gordon Wilson of Chicago (personal communication) in discussion on Hallenger Howard. *Petrotic Arch. Otolaryng.* 17: 725 (May) 1933. (See H. N. Microscopic Observations of the Petrous Apex. *Ann. Otol. Rhin. & Laryng.* 42: 175 (March) 1933. The author says: "The laboratory possesses one specimen (four years of age) in which no mastoid infection may be observed but a severe osteomyelitis is present in the apex with dehiscence of the cortex."

of the clavus of the sphenoidal base. In the center of the carious area there was a hole which passed through the petro-occipital articulation and entered the pharynx mesial to the transverse part of the carotid artery.

During life the patient had not complained of his throat, and careful inspection showed only "thickening of the lateral pharyngeal wall" on the side of the osteomyelitis. Apparently a pinhole perforation, so small that it was undemonstrable even at autopsy, had allowed air to enter the extradural abscess, as the roentgenogram showed the large defect in the bone filled with air.

Out of about fifty verified cases of suppuration within the petrous apex, I have had six cases of osteomyelitis below the carotid, so the condition is far from infrequent. Of the six, only three caused a demonstrable fluctuating swelling in the pharynx. The other three cases presented large collections of pus below the carotid artery inaccessible to any operative approach from the aural region but probably curable by boldly perforating the bone of the petrous apex in the lateral pharyngeal roof mesial and slightly posterior to the eustachian tube.

SYMPTOMS

Osteomyelitis of the Petrous Base—This is characterized by a disappearance of all apex meningeal symptoms with a continuation of the signs of bone sepsis, because the suppuration is under the carotid artery and away from the dura.

As in all osteomyelitic cases of the apex, there are signs of venous sepsis—a chill or a chilly sensation followed by an up and down temperature at the time of invasion, leading to a diagnosis of lateral sinus thrombophlebitis, and the jugular has been ligated by the attending otologist in more than one instance.

Exploration of the sinus fails to reveal any clot.

If an osteomyelitic focus suppurates and extends to the surface, the resulting abscess is in the vault of the pharynx behind and mesial to the eustachian tube.

Pharyngeal Symptoms—In one of my cases slight difficulty in breathing on one side, disregarded by the patient himself, was the only throat symptom. And in a boy the pharyngeal swelling was discovered because he volunteered the information that a drop of water came out of his nose when he swallowed in a sitting position.

There is no difficulty in opening the mouth, as is characteristic of pharyngomaxillary abscess, the abscess forming posterior to the internal pterygoid muscle.

CONCLUSIONS

1 In every case of apical suppuration the lateral pharyngeal wall should be inspected frequently, as a perforating abscess from caries of the base gives few or no symptoms.

2 Osteomyelitis from aural suppuration limited to the petrous base below the carotid and the region of the petro-occipital articulation is a distinct entity. It can be diagnosed before the advent of meningitis, which is inevitable unless the suppuration "eats" through the thick bone of the base and discharges into the lateropharyngeal roof or unless the bone is surgically perforated.

3 A technic has been anatomically evolved for the surgical perforation of the petrous base, through the mouth under the sense of sight for drainage of suppuration below the carotid artery.

ABSTRACT OF DISCUSSION

DR. GEORGE M. COATES, Philadelphia: The subject of petrositis is a comparatively new one, and great credit for its present prominence must be given to the pioneers Profant, Eagleton, Kopetzky and Almour, and others. Many divergent opinions regarding the anatomy, etiology and pathology of this condition were discussed, but in the last few years the whole subject has become much more clarified.

Gordon Wilson believes that pneumatization proceeds only from the already developed mastoid cells, that it cannot, in most cases, proceed actually into the apex during the growing period of the pyramid—that is, up to 15 years of age—that the majority of the pyramids, at least in his series of more than fifty cases, contain mostly marrow-containing or diploetic bone, and that the resulting lesion was therefore osteomyelitis. Cavities may be found at operation or autopsy, but these may be destructive bone lesions, abnormally large and infected marrow spaces as well as empyemas in pneumatic cells. Infection of the diploetic bone could have taken place by continuity but would be more likely the result of infection along the blood and lymph channels. The latter route has not been thoroughly studied. Symptomatology will vary according to the route of extension as well as the type of development, not only of the pyramid but of the mastoid process and the tympanic cells. Surgical approach must vary with the type and location of the disease, as must the entire management of the case. Many petrosal infections clear up without radical surgery, but we must prepare ourselves to recognize these cases for otherwise we shall lose patients because of waiting until the operative time has passed. Dr. Eagleton is chiefly concerned with osteomyelitis and calls attention to infections in the floor of the pyramid, in relation to the sphenoid and often associated with pharyngeal manifestations. Such cases usually occur in infants and children before adult characteristics of the bone have developed. The importance of this work, another phase of petrositis, cannot be overstated, because these cases are very apt to be overlooked until intracranial signs have appeared, or even after they have appeared, because of the obscurity of the lesion in the light of our present knowledge and because of its inaccessibility. As Dr. Eagleton has pointed out in a previous paper, osteomyelitis has a tendency to self cure through the protective mechanism of the red bone marrow, a reticulo-endothelial structure. Pneumococci and hemolytic streptococci are the dangerous infective organisms, but a latent osteomyelitic process may be converted into a fulminating one by injudicious surgery.

DR. HAROLD I. LILLIE, Rochester, Minn.: That great good has come from the pioneer work of Profant, Eagleton, Kopetzky and Almour in calling attention to the clinical significance of petrositis must be readily admitted. Baldenwack in 1908 described the surgical approach that I suggested in 1932. The work of Baldenwack was unknown to me then, and so that I may not be accused of plagiarism I hereby gladly make acknowledgment of his priority. "Petrositis" is a good term. It is descriptive, inclusive, and covers both osteitis and osteomyelitis. The sources of development of the cells that extend into the pyramid should be fundamental knowledge. It is well to emphasize the importance of any pain, headache in any situation and continuous discharge. If the clinical symptoms and signs give preoperative suggestive evidence of the tract involved the surgical approach should be considered to be indicated. Rather than depend on repeated myringotomy for adequate drainage it would seem safer to perform a radical type of operation on the mastoid in order to be sure that drainage would be continuous. I am not certain that extensive involvement on the under surface of the pyramid can adequately be exposed except by intracapsular destruction of the pyramid, a formidable procedure. A few years ago I suggested that the term "simple mastoid operation" was poorly chosen because of its implications. I suggested that the term "complete mastoid operation" more nearly met the requirements of good surgical principles suggested long ago by Küster. That is still my idea even more strongly fixed than previously. How ridiculous it sounds to suggest that an operation seeking out the cellular extensions into the pyramid is a simple operation. I reserve the term "simple mastoid operation" for the procedure in which the tympanic antrum of children is opened. The mastoid operation

that was done generally some years ago probably could be called simple, for instance, when a subperiosteal abscess was opened and the defect through the cortex was simply enlarged for drainage. The correct interpretation of surgical pathologic change found at operation is important. In the type of case under discussion, if the surgeon expects to find fistulous tracts in the sense that pus will be found escaping from the situations suggested, his disappointment will be great. He more likely will find red, granular areas in the cancellous bone, which, when followed to white, nonbleeding bone, may lead to an abscess or to a region of osteitis. If a definite tract is encountered without purposeful search, adequate operation should be easily accomplished. In the past, meningitis from petrositis has been the cause of death in many cases in which the mastoid wounds apparently had healed and in which the untoward signs and symptoms may not have been recognized.

DR MERVIN C MYERSON, New York. I am in favor of scrapping such terms as "hypotympanic" and "epitympanic" and "supralabyrinth" and "infralabyrinth" for localized areas in the middle ear and mastoid. There are cellular tracts in the middle ear, there are prefacial and retrofacial cells, the retrofacial cells being inferior to the posterior canal, occasionally we find cells posterior to the posterior canal. A review of the literature has shown that a majority of the demonstrated fistulous tracts that have been found at operation and at autopsy were in relation to the superior canal. Twenty-nine of fifty-three fistulas which I collected from the literature were either anterior to the superior canal or posterior to it. Therefore it would seem that the first place to look for a fistula would be in that area. There seems to be a misconception as to what constitutes a fistula. The average man feels that there is an outpouring of pus through one of the cellular tracts. This is not the case. The reason these patients have pain behind the eye, or frontal headache is that the cellular tract through which the infection traveled into the petrous apex is blocked by granulations. Therefore one can't expect much, if any, discharge. A good deal of the profuse discharge from the middle ear in many of these cases is not necessarily from the petrous bone or the apex. Because there is infection in the petrous pyramid collateral vascular changes occur in the middle ear which are conducive to increased exudate. I have found that there are two types of infections of the petrous apex. The one is the trapped empyema, a trapped collection of pus in which the patient invariably gets well if the pus is evacuated, the other is the type Dr Eagleton has spoken of. I mean the granuloma forming type of infection. Two weeks ago a young girl had pain behind the eye and a little elevation of temperature and trouble in the petrous apex. I found no pus there. Instead I found the petrous apex area entirely replaced by granulation tissue and there was no longer any bone present. The inferior aspect of the petrous bone which Dr Eagleton speaks of would seem to become infected more frequently by a fistula that travels into the apex area from the area below the level of the horizontal canal that is, in the so-called jugular bulb area, when the jugular bulb is much below the level of the round window, or the suboclear area anteriorly. In 1924 Friedenwald of Baltimore reported a case that has not been cited in the literature until recently in which a man had a ninth, tenth and eleventh nerve involvement and severe headache for several weeks. He had a laryngeal paralysis on the same side. The symptoms did not subside until the abscess ruptured spontaneously. Several months later he still had his laryngeal paralysis.

DR H J PROFANT, Santa Barbara, Calif. It seems to me that if we have a word that is somewhat dramatic for the medical profession as a whole it attracts their attention and as Dr Lillie mentioned it focuses one's attention. It is at the same time an inclusive term.

With regard to the tracts, I had the same difficulty. One mentions suboclear and the various types and the audience gets dizzy. One tells them about the epitympanic space and they respond. Tell them about the antrum and they are with you. Of course in our own group we can go into these fine terms but when one wants to describe it to others one has to make it as simple as possible.

DR WELLS P EAGLETON, Newark, N. J. I am pleading for a complete unlocking of the petrous pyramid. Thus one sees

every tract that may lead into the apex. The cases discussed today do not go on to recovery unless something is done that is not in the books. They generally begin with an osteomyelitis of the apex situated in the superior portion where an abscess generally occurs, but the medullary substance of the bone accomplishes the cure of the infection in the superior area leaving however an area below the carotid canal that forms an abscess. I had a patient who had been to three eye doctors because of ocular pain with an abscess of the throat from an osteomyelitis of the apex. No one asked him about his ear. His ear did not bother him. Three days after he visited the last doctor, he died from fulminating meningitis.

There is something to be said in favor of all operative procedures in different cases, but osteomyelitis confined to the inferior surface cannot be reached by any aural approach.

In all operations around the petrous apex, one may tear the dura. If the dura is torn in one particular place it may cost the life of the patient. The dangerous place for a tear is just where the middle and the posterior fossae unite. The smallest pin-hole opening in that point lets out a little cerebrospinal fluid. Nothing is thought of it because one wants the cerebrospinal fluid out, but, if the opening is watched, one will see it go back and forth. There is a little pulsation, and this pulsation sucks infection into the subdural space. If it is a pneumococcus type III case, the next day the patient has a fulminating meningitis. To correct this defect I wanted a tissue that possesses local immunity. I argued that the submucosa beneath the mucous membrane of the mouth on the inner side of the cheek must possess such properties. I remove a piece with forceps from the inside of the mouth, cut it off freely and place it against the dural defect while still in the forceps. It unites immediately. This repair should be done uniformly. I have stopped two cases of discharging cerebrospinal fluid immediately by this method and I recommend it. It is simple and takes only a minute to do.

THE PHYSICIAN'S PLACE IN THE HEALTH PROGRAM

W W BAUER, MD

Director, Bureau of Health and Public Instruction, American Medical Association
CHICAGO

The place of the physician in a community health program must be a central one. Public health relies in the last analysis on medical science. It is true other sciences are called on and that nurses, statisticians, educators, administrators and engineers make their contributions to a program of public health, but without the correlation furnished by medicine, progress toward better health would not ensue. There are nine reasons why the physician must be a central figure in any successful public health program.

The objective toward which physicians, health officials and voluntary health workers are attempting to lead the people is essentially an idealistic one. The conception of better health for all with consequent economic, social and spiritual advantages to the healthy individual or group, is an ideal which was held by the medical profession as long ago as Hippocrates, whose aphorisms deal not only with the recognition and treatment of disease but with a philosophy of better health. Physicians have always exemplified this constructive idealism sometimes to the extent of martyrdom. Michael Servetus was burned at the stake for religious and scientific heresy, Edward Jenner was reviled and ridiculed, Oliver Wendell Holmes and Ignaz Semmelweis were ignored, William Harvey was branded a quack, Ronald Ross struggled alone toward the conquest of malaria and the modern physician sets his

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

face with idealistic determination against a wave of socialistic collectivism which threatens to engulf him along with the community.

A successful program toward better health demands idealism, but it must also be a practical movement. The feet of the workers must be firmly planted on solid ground. The experience of the physician with the complexities of the human organism and the endless complications involved in its relationship to the environment cause him to develop a spirit of conservatism and caution. He is not always ready to concede that a single influence in the community will bring about revolutionary changes in disease conditions. He demands proof. Sometimes this makes him seem reactionary, but numerous instances might be cited in which a little more conservatism might have prevented ridiculous errors or even serious mistakes. Witness the enthusiasm with which toothbrush drills were promoted in the schools, observe the persistence of baby contests promulgated in the name of health, consider the widespread introduction of dinitrophenol for reducing purposes and its aftermath of cataract and other catastrophes. A little more conservatism, a little more critical scrutiny, a little less haste would have saved us from the ridiculous fiasco of toothbrush drills, the commercial racket of baby contests and the ghastly menace of dinitrophenol. The conservatism of the profession makes it an easy mark for lampoons by the thoughtless or the unscrupulous, but this very conservatism can be a valuable balance wheel which will help to keep the practices of public health within the bounds of scientific accuracy.

Idealism and practical experience require opportunity for expression. No one in the community has a greater opportunity than has the physician. One of the greatest problems of the health administrator is how he may reach the groups to whom he knows preventive measures must be applied, if they are to be effective. The well trained public health official knows that his tuberculosis work must be done among those exposed to tuberculosis, he realizes that diphtheria and smallpox immunizations must be carried out in the preschool group and preferably during infancy, he is quite aware that his educational efforts for better maternal hygiene must reach the expectant mother, he knows that control of venereal diseases depends on a knowledge of when, where and under what circumstances they occur. There is no group in the community which can more effectively bring together the public health worker and his desirable clients than can the physician. It is he who knows where preventive measures among his patients are most needed. It is he who can bring them most effectively to his patients. He needs the public health official, and the public health official needs him. There is no success for the public health official who ignores the medical profession in his community. Neither is the fullest measure of service possible to the physician who ignores his obligations toward preventive medicine. The public health official and the physician are natural cooperators, more and more the best trained health officials and the more progressive physicians are realizing this and are sitting down in conference to make their ideals bear practical fruit.

The medical profession as a whole has always accepted its obligations toward the public in a spirit of idealism tempered by experience. Among the earliest records of interest in the public health in the United States by organized groups of physicians are the reports

of the yellow fever outbreaks which attacked New York and Philadelphia in 1793. In the *Transactions of the American Medical Association* for 1849 is an extensive report by the Committee on Public Hygiene¹ in which are discussed such questions as drainage, street cleansing, water, housing and ventilation, nuisances, disinfectants, and other matters relating to public health and hygiene. It is not generally known that the American Medical Association had a large part in the early development of the highly significant movement toward appraisal of public health work. The forerunner of modern appraisal methods was a report on state public health work carried out under the direction of the Council on Health and Public Instruction by Dr. Charles V. Chapin,² commissioner of health of Providence, R. I. Dr. Chapin's report was published in *THE JOURNAL* and reprinted in a valuable reference book which is much in demand, though now out of print except for a few precious copies. It is significant that this reference to the beginnings of public health work in the several states credits the beginning in many instances to the medical profession or to individual physicians. In many states, especially in the South, public health work is virtually directed by the medical profession. It is not intended, of course, to convey the impression that all physicians have met their obligations for community service, nevertheless the profession, as a whole, has been responsible for the initiation and continuance of much valuable work in public health and is now cooperative in many phases of it. This cooperation is illustrated by relationships which have been established by the American Medical Association through its Bureau of Health and Public Instruction with the National Education Association, the General Federation of Women's Clubs, the National Congress of Parents and Teachers, the National Committee for Boys and Girls 4-H Club Work, the State and Territorial Health Officers, the United States Public Health Service, the United States Children's Bureau. State and local medical societies are now working with local units of the National Tuberculosis Association, the American Society for the Hard of Hearing, the American Society for the Control of Cancer, with state and city health departments, schools, civic organizations, women's clubs, parent teacher associations, and other local groups too numerous to mention.

Public health, in common with all other branches of medicine, rests on research. Without research there is no progress. The medical profession, individually and collectively, has always been in the forefront of research. The existence of the Scientific Assembly and the Scientific Exhibit of the American Medical Association are in themselves powerful stimuli to research. *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* and the eight special journals offer opportunity for the publication of significant contributions. The Association itself makes grants in support of research. Significant contributions to research are made by representative members and Fellows of the Association and their allied workers through research laboratories in medical schools, governmental establishments and other institutions. Organized medicine has not only encouraged and participated in research but has defended it against the villainous attacks of the antivivisectionists who deck themselves in furs and

feathers while they shudder at the thought of stimulating the muscle of a dead frog with an electric current. Legislation intended to cripple medical research has been fought in the Congress of the United States and in the several state legislatures by research workers and medical societies. The influence of organized medicine has consistently been exerted in defense of an apathetic public which has not yet realized how its security is threatened by a small noisy group of fanatics.

The physician knows community health needs in a peculiarly intimate manner possible only to physicians and the clergy. The statistics of public health are built up from observations and reports originated by physicians. The United State Public Health Service carries in *Public Health Reports* the standing heading "No health department, state or local, can effectively prevent or control disease without knowledge of when, where and under what circumstances cases are occurring."³ This is as true of other health problems as it is of communicable diseases. The intimate relationship of the physician with the patient, which itching reformers would like to destroy and replace with a bureaucracy, renders the physician better able to understand the real health problems of the community than any one else. Some of the problems that have failed of solution by existing methods are being attacked by new methods in which the physician is the central figure. A case in point is syphilis, which has been characterized as the next point of attack in public health. Reporting of syphilis has not been successful, quarantine of syphilis has found few with the courage to attempt it, treatment of syphilis in public clinics has been only partially successful in controlling the scourge. Now the attack is being concentrated through the channels of medical practice. In this plan, the privacy of the patient is respected and he need confide only in his doctor. If he is unable to bear the expense of treatment, community help in the form of laboratory service and free materials is available through the family doctor. Where this plan has been given a genuine trial, there is evidence that a reduction in syphilis has actually begun and may be expected to continue.⁴

The physician must have a central place in the public health program because he commands public confidence. The ancient ideals of the medical profession have been made the butt of gibes by irresponsible magazine writers, who cannot or will not understand that a profession may actually be motivated by a genuine and unselfish regard for the public interest. Despite these superficial evidences, there is plenty of indication that the fundamental confidence of the people in their doctors remains unshaken. Every health officer knows that his recommendations for immunization and other preventive procedures are regularly checked by mothers against the opinion of the family doctor. This is as it should be. It must be encouraged and extended.

Another field in which the physician can make great contributions, has made them and continues to make them, is health education. Since the very beginning of medical practice, it has been the habit of physicians to advise their patients not only about treatment but about prevention. This has been a person to person relationship, and this relationship will continue to be necessary in our attacks on the great health problems

of today, namely, cancer, apoplexy, kidney disease, syphilis, diabetes, heart disease and the evils of self diagnosis, self medication and the nostrum racket. The fight against quackery has been prosecuted with more vigor and success by the medical profession than any other agency. The only authentic health magazine for lay readers, with nation-wide circulation, is published by the medical profession. The only nation-wide dramatized radio health program of noncommercial character is a joint contribution to health education by the American Medical Association and the National Broadcasting Company.

The picture I have tried to paint is not a completed canvas. Not every physician measures up to the ideals that have here been pictured, but the profession, as a whole, may fairly be said to have done so. It is not a finished picture, neither is it merely a dream toward which nothing has been done in the way of fulfillment. It is a sketch of which the larger outlines are definitely visible but in which many details need to be filled in. The challenge to the practicing physician of today is to take that central place in the public health program in his community which belongs to him by right of tradition, training, qualifications, and public interest and necessity.

535 North Dearborn Street.

ABSTRACT OF DISCUSSION

DR. GEORGE M. LYON, Huntington, W. Va. That the physician should occupy a central place in the community health program is appreciated more clearly today than ever before. Attempts to promote medical participation in community health matters as an organized program are being initiated with increasing frequency. Such attempts indicate the desire of the medical profession to go along in the promotion of improved community health programs. It is not always easy for the individual physician to see just where his particular responsibility lies. Much of the time it is because in his medical training he was not encouraged to develop that philosophy which would enable him to understand just what his specific responsibility might be. At other times it is because the local health officer fails to understand the importance of bringing the individual physician actively and sympathetically into the program. There is no more effective way of blocking progress in a health program than by antagonizing the local medical profession or relegating the individual physician to the background. Health officials who will provide the leadership and the opportunities for the local physicians to participate in the public health program in an organized way will do much to promote health protection. When such organized participation occurs, the physicians are generally quick to sense and in a constructive manner to accept their individual responsibility. Where health officers provide leadership in such programs, much will be accomplished in promoting that team work which is so essential between the medical profession and the official health program. It is essential that every effort be made to clarify in the minds of the physicians and official health workers just what the functions of the public health program, the school health program and the medical relief program are. I believe that this differentiation must be made in order to clear up the confusion generally encountered not only in the minds of laymen, but likewise in the minds of the physicians and health workers. Public health leaders are particularly aware of the misunderstanding that the average physician has about what is the function of the public health program, of the school health program and of the medical relief program. The confusion resulting from having the medical relief added to the public health program has been very detrimental to the development of proper public health programs. We have attempted in our own local county society to administer the school health program. In it a clear distinction is made between the essential objectives of the three programs.

³ *Pub. Health Rep.* 51: 340 (March 27) 1936.

DR. STANLEY H. OSBORN, Hartford, Conn. I was hoping that Dr. Bauer's paper might tell us how to do the things he is talking about. All of us want to do what Dr. Bauer has outlined, namely, to bring about a closer cooperation between the physician and the health officer. That is what we are really trying to aim at, to get our city and state societies associated with committees of state health officers, or the city health officers. Such a state of affairs would make it possible to tackle a new problem like, say, immunization against undulant fever. We as health officials are trying to think of the medical men and the medical societies as our right hand or part of us in carrying out this public health work. By doing that we shall automatically accomplish the right thing the way we see it not only as health officers but also as physicians, and the result will be not only a program but a program of physicians and of health officers.

DR. W. W. BAUER, Chicago. I was careful not to get down to particulars, as Dr. Osborn remarked, because I was conscious of the fact that particulars are one thing in Connecticut and another in New Mexico. In the last few weeks I have visited New Mexico, Arkansas, Alabama and Washington, D. C., besides being in Chicago, and the tremendous range of different conditions that one encounters in such a series of trips convinces one that there is absolutely no way of arranging cooperation in accordance with any one plan. Dr. Lyon has pointed out a way in which they have done it in West Virginia. If you write to different places, of which a few come to mind now, one being Nassau County, N. Y., the Medical Society of New York and the Medical Society of Wayne County, Mich., and the Detroit Health Department, you will find different ways of doing things, and yet they are all based on the same fundamental principle. Here and there county societies and health commissioners are taking steps to get closer together. In many places it seems to be desirable to have a community health council. There is an excellent report on community health councils by Professor Hiscock of Yale, which deals with the Allegheny County situation in Pittsburgh (Appraisal of Public Health Activities in Pittsburgh, Pennsylvania, 1930-1933, Pittsburgh, Federation of Social Agencies of Pittsburgh and Allegheny County, 1935, \$1). It shows how a community of people have sat around a conference table and studied their situation and evolved ways to meet their needs. There was an exhibit in the Scientific Exhibit at which it was possible to get diagrams of a health conservation set-up here in Kansas City. I want to emphasize that in mentioning these particular instances I have no intention of creating the impression that these are the only ones. There are many others that are accomplishing the same quietly and unostentatiously, and perhaps without any conscious plan the health department and the medical society are getting closer together for mutual cooperation. It used to be taken for granted that there was cooperation. There was a time when we were far apart, and yet today we find a gratifying number of health officers who are members of this section of the American Medical Association, as well as a gratifying number of American Medical Association members who belong to public health organizations. I hope that that will continue and that every possible means will be employed to avoid misunderstandings and that we foster and create cooperation and good will in the interest of public health.

Syphilis Almost Rare in Sweden.—The commission was convinced that syphilis has decreased in prevalence in Sweden to the point where one may refer to it as almost a rare disease, there having been reported in 1934 only 1 new case in 14,000 population, a case rate of 7 per 100,000 population as compared with a case rate of 20 per 100,000 in Denmark. Lacking a basis for comparison with case rates in this country this would indicate that syphilis is as rare in Sweden as typhoid fever now is in New York City.—Report of the New York City Commission to Investigate the Prevention and Control of Syphilis and Gonorrhea in Scandinavian Countries and in Great Britain, *Am. J. Syph. Genor. & Ven. Dis.* 20:37 (July part 2) 1936.

ATHLETIC INJURIES

MARCUS H. HOBART, M.D.

EVANSTON, ILL.

Owing to the present widespread interest in athletic the study and care of athletic injuries is forcing itself more and more on the attention of the medical profession. We as physicians cannot hastily brush them aside, treating them like any ordinary injuries, but must appreciate that they are in a class by themselves and demand special attention.

The athlete, whether college or professional, has a relatively short life in this capacity. A college athlete's span of activity is limited, as a rule, to three years, or at most four, with a few notable exceptions. While a professional athlete's tenure of office may extend through three or four presidential terms, most of them end before the year that national presidents are eligible to hold office. While their life may begin at 40, their athletic prowess or usefulness ends by then.

This short span of athletic usefulness demands, therefore, that the acme of fitness during its existence. The treatment of athletic injuries is therefore essentially the treatment of traumatic conditions with the added necessity of getting the athlete back into shape as quickly as possible. It is important from the athlete's standpoint to return him to his team quickly and 100 per cent recovered, but the most important requirement is to return him safely. The latter from a purely medical standpoint is the real requisite, i. e., to have the athlete return to practice and play only when it will do him no damage. The situation can be compared to the medical one in France during the World War. The medical officers were required to return the wounded soldier in condition for the front line trenches as quickly as possible, apparently with the fear that the war might end too soon! The doughboy must not only be repaired but repaired without delay, so that he could stop a few more bullets before he escaped. The athlete, however, is most anxious to get back, as actually his athletic life depends on it.

In the prevention of injuries there are many important points to consider.

In the first place the physician should be in full control of the physical side of the team, as the head coach is in charge of the athletic side. They should work together. Under the doctor and the coach there should be trainers, masseurs and physical therapists whose duty it is to keep the men in condition, but any special treatment should be prescribed by the doctor and supervised by him. Complete harmony should exist between all those in charge.

All athletes should have a physical examination at least each season. The heart, pulse and lungs should be checked over, examination made for hernias, and any other abnormalities noted. There should have been a recent successful vaccination against smallpox. These things are done each fall at Northwestern.

All injuries should be reported immediately to the team physician. Players, trainers and coaches should get it into their heads that they will save time and benefit the team by getting help from the doctor. It

Read before the Evanston Branch of the Chicago Medical Society April 2, 1936.
From the Surgical Department of Northwestern University Medical School, Chicago.

is thus possible to save many days of disability and actually get and keep men in play, or for important games, who never could have played had they delayed reporting

After reporting, a player should take only such treatment as the doctor prescribes. As Dr Marvin Stevens¹ says, "many a player has been severely injured by having ignorant trainers, players or coaches try to 'jerk something back' in place about which they knew nothing, when a skilled physician could have fixed the player without damage."

It is not necessary to enter on a diatribe against the various cults, but it might be said that there have been numerous illustrations of the harm done to athletes by those all too willing gentry

The coach's particular job is in preventing injuries, first, by getting the men into good physical condition before contact work is assumed and, secondly, by teaching his men how to take care of themselves on the field, especially in football. They should be taught the proper methods of tackling, blocking and falling. Stevens's book takes these up in great detail. It is true that many injuries, if not most, occur in an awkward, green player, or one who is off his guard, or loafing. Of course there are notable exceptions. Thirdly, proper protective equipment should be worn by players at all times.

Now for the actual care of injuries. A good athletic doctor, like all physicians, has the patient's interest at heart. In treating athletes he may allow a little more latitude in his care, but he should always see to it that no permanent or serious injury is the result of returning too soon to active play.

With this in mind, serious injuries are treated as such. A fracture practically always keeps the player out. Like any other fracture, it requires emergency splinting and treatment. Reduction should be done at a hospital with x-ray equipment, and fixation should be maintained long enough. Practically always a cast should be used rather than a splint, as the cast cannot be so easily removed. The general rule is to use a cast for children, athletes and idiots—and recently there has been added to this list a fourth—doctors.

Another very important part of fracture treatment in athletes is the subsequent care. Mobilization is

TABLE 1—Conditions Treated

| Year | Totals | Injuries | Inflammations |
|--------|--------|----------|---------------|
| 1930 | 133 | 99 | 36 |
| 1931 | 134 | 100 | 34 |
| 1932 | 183 | 101 | 37 |

| Totals | 657 | 558 | 129 |

important. In ten days after reduction and at least biweekly thereafter, the limb should be removed from the cast, manipulated, active and passive motion used, and physical therapy soon instituted. Massage and diathermy are used in every case. This gets the muscles toned up, so that when the bone is healed function will be present without delay.

Skull fractures and neck fractures should keep the athlete out of play at least for the season, usually for a year. In many minor fractures, with adequate protection the players may be allowed to carry on sometimes

These may include fractures of the phalanges, hand, wrist, forearm, fibula, and even ribs and clavicle on occasion. Once a player with a fracture of three transverse vertebral processes was allowed to return after three weeks' rest in a cast. This is rather too risky.

Sprains, although not so serious as fractures, give much trouble. The usual offending joints are the ankle, knee, shoulder and phalangeal. Prophylaxis demands protection. The ankle is strapped by means of the basket-weave with adhesive tape.² This has been done

TABLE 2—Types of Injuries

| Year | Fractures | Sprains | Contusions Concussions | Dislocations | Lacerations | Inflammations | Cartilage | Operations | (Majors) |

| Totals | 100 | 167 | 127 | 24 | 56 | 129 | 71 | 177 | (44) |
| | (3) | (1) | (2) | | (5) | | (4) | | |

The figures in parentheses show the relative frequency

for every game and scrimmage very effectively at Northwestern. The shoulder is protected by a leather shoulder pad, worn under the sweater. Knees may be strapped with adhesive tape but are almost impossible to protect adequately. Hinged braces help somewhat but for the most part are too cumbersome and are not adequate. Adhesive tape about the wrist will give some protection.

When a sprain has occurred in any joint, I have it packed first in ice whenever possible. It is then fixed snugly with adhesive tape or a bandage. Procaine hydrochloride has not been used, but it may be justified in view of Leriche's³ recent work. The ankle is strapped with pressure on the tender sprained spot. For the knee the adhesive strapping lengthwise, criss-crossed with a pad on the tender spot and a half inch thick cotton bandage over all, is useful. The shoulder is sometimes strapped, with the arm to the side, or the arm carried in a sling, neither of which is very satisfactory. If these joints do not respond to this treatment, they are put at rest in a cast for six weeks. Mobilizing and after-treating is done as in a fracture. Players with these sprains are sometimes allowed to carry on through the season and casts not used until afterward. There have been very few severe sprains that would not respond to this treatment.

Contusions and bumps are usually treated first with ice and later with heat. Sometimes a "hot pack" is applied over night. This consists of glycerin or analgesic balm and tends to keep the swelling down. Later contrast baths, diathermy and massage are used. Most contusions respond to this treatment quickly.

Dislocations occur chiefly in the shoulder, elbow and phalanges. These should be reduced immediately, theoretically after an x-ray examination shows no fracture. It is poor treatment to leave a joint dislocated any length of time when it can be reduced easily. After reduction the joint should be held at rest for two or three weeks, with some motion after ten days. This rest is important to obviate a myositis ossificans, especially in the elbow joint.

¹ Stevens M. A. and Phelps W. M. The Control of Football Injuries. New York, A. S. Barnes & Co. 1933.

² Lewis Dean. Practice of Surgery, vol. 2, chapter 5, pp. 43-44.

³ Leriche Rene and Aenulf G. The Treatment of Sprains by Interligamentary Injection of Novocaine. Am. J. Surg. 32: 45-47 (April) 1936.

Myositis ossificans is one of the arguments in favor of rest after injury, not only in dislocations but in sprains about the joint and in contusions. A "charley-horse" in the thigh is a potential myositis. These are treated first with ice and then with diathermy and rest, if need be in a cast. Operative removal of the newly formed bone is advised only after the condition is quiescent, if bone is formed in the quadriceps muscle and if pain or loss of function persists. A cast and diathermy will take care of most of these, without massage.

In recurrent shoulder dislocations the combination operation is used—a Clairmont combined with a

Nicola.⁴ This has given success in two cases and must be tried more to be proved. It does seem to be the most physiologic and at the same time most complete of any operation so far devised.

Lacerations and cuts are cleaned out thoroughly and closed loosely with a drain inserted and a wet boric acid dressing applied for twenty-four hours. The question of antitetanic and antigas serum is always to be considered. Sutures about the face are removed in from three to five days to prevent stitch scars, unless the player is to scrimmage or be in a game, when the sutures are left in longer. Bandages on the face only excite opponent players of certain types to tear them off. Consequently during the game a collodion dressing is used which is removed immediately after.

All scratches and cuts are dressed as soon as possible with an antiseptic dressing, after cleansing. Inflammations require hot boric acid dressings or hospitalization, if continued.

A word about the knee is indicated, as there are more injuries to the knee than to any other part. Because of the careful protection given ankles, the knee perhaps suffers as a consequence. With the ankle strapped properly it is protected, and this puts more strain on the knee. It is important to diagnose a knee injury correctly and differentiate a contusion, a sprain, semilunar cartilage injury and a fracture. This can be done if one does not omit the x-ray examination. Of the 110 knee injuries in the five year period investigated, seventy were diagnosed cartilage injuries and twenty were operated on. All recurrent semilunar cartilage injuries require removal of the meniscus. This should give a knee functioning 100 per cent. Athletes can be named as postoperative illustrations, playing football, basketball, handball and tennis or engaging in track athletics without handicap. This operation, while delicate, is safe when done by some one experienced. One would not choose to have the knee operated on by an inexperienced general practitioner or by most surgeons, as considerable damage can be done. A special knife and scissors are used and many of these cartilages come out through a small incision.⁵ If the cartilage has been dislocated only once, reduction and fixation in a cast for six weeks may be tried, if twice or more, operation is indicated.

Besides these usual injuries, there have been many unusual conditions: nerve injuries with paralysis of the brachial plexus and of the peroneal nerve, the latter requiring operation, a halfback with a gunshot injury of the left hand, resulting in a compound comminuted fracture, treated by debridement and diluted solution of sodium hypochlorite (modified Dakin's solution), with complete recovery, a cheer leader with a sprained wrist from yelling, a golf player with tuberculous pleurisy, several college athletes with concussion of the brain, a football captain with smallpox, a football player acting as a life guard when a moth flew into his ear and, being dart shaped, could not back out. This probably would not have occurred had both the athlete and the moth stuck to their proper elements.

A complete detailed statistical report is not included, but a five year period from 1930 to 1934 may be selected arbitrarily from twelve years' experience in treating athletes at Northwestern University. During this five year period 687 cases were treated, of which 558 were injuries and 129 inflammations (table 1). The inflammations or infection cases include anything from furuncles and boils to a case of osteomyelitis of the femur. This last was a flare-up in an old quiescent osteomyelitis. A debridement was done, packing with petrolatum being employed according to Orr's method.⁶ Good recovery ensued. It is noteworthy that the number of infections treated has fallen off from thirty-six in 1930 to ten in 1934. This may be attributed to the fact that the trainers have been taught to dress the minor conditions properly and to send the more severe cases in immediately for proper surgical care.

Of the types of injury (table 2), sprains lead with 167, followed by contusions and concussions 127, fractures 109, cartilage injuries 71, lacerations 56, disloca-

tions 24 One hundred and seventy-seven required operative or surgical procedure, including suture of lacerations and plaster casts, and forty-four major operations, which include herniotomies, appendectomies, knee cases, recurrent dislocation of the shoulder, osteomyelitis, and nerve and tendon surgery

As to the anatomic location of the injuries, the knee leads by a remarkable majority of 110 (table 3) This is partly due to the exposed position and the inability to protect the knee, to the fact that both direct and indirect force can affect the knee and perhaps to the fact, as has been said, that the ankles are well protected and do not give way, resulting in the force being trans-

TABLE 4—Number of Casualties

| Year | Football | Basketball | Baseball | Wrestling | Track | Tennis | Swimming | Miscellaneous | Yell | Water Polo | Boxing | Golf | Tumbling |
|--------|----------|------------|----------|-----------|-------|--------|----------|---------------|------|------------|--------|------|----------|
| 1930 | 60 | 8 | 11 | 14 | 9 | 1 | 2 | 2 | | | | | |
| 1931 | 61 | 9 | 9 | 12 | 7 | | 3 | 3 | | | | | |
| 1932 | 70 | 8 | 6 | 10 | 5 | | 2 | 1 | 1 | | | | |
| 1933 | 60 | 10 | 5 | 16 | 7 | | 3 | 12 | | 6 | 3 | | |
| 1934 | 97 | 15 | 4 | 16 | 2 | | 6 | 1 | | 3 | 4 | 1 | 1 |
| Totals | 368 | 50 | 35 | 70 | 30 | 1 | 16 | 9 | 1 | 9 | 7 | 1 | 1 |
| | (1) | (3) | (4) | (2) | (5) | | (6) | (7) | | (7) | (8) | | |

mitted to the knee It might be better not to strap the ankles so tightly Next in frequency to the knee injuries come those to the digits, fingers and toes, sixty-six in all, then ankles fifty-three, shoulder and nose with forty-five each, hand thirty, wrist twenty-six, face twenty-five, elbow twenty-four, back and leg twenty-two each, and foot twenty-one The other regions had less than twenty, dwindling down to one each of the coccyx and perineum

The last table of especial interest to coaches, perhaps, is that of the number of casualties in each sport (table 4) As is to be expected, football leads with 368 If it is realized that probably five or six times as many play football as any other sport, this will not sound so bad Next to football comes wrestling with seventy, basketball fifty, baseball thirty-five, track thirty, swimming sixteen, water polo nine, boxing eight, tennis, golf and tumbling one each

Further analysis might be made to determine which sport or anatomic locations sustained the most severe injuries

SUMMARY

1 Athletic injuries demand special consideration by the medical profession as they are in a class by themselves

2 It is necessary for an athlete to obtain a quick but none the less complete cure

3 Certain advances have been made in the treatment of specific athletic injuries

4 This review includes twelve years' surgical experience in handling athletic injuries at Northwestern University

5 Detailed statistics cover a five year period (1930-1934) during this time

6 In treating or coaching athletes it should always be borne in mind that all serious or permanent disabilities should be prevented and that the individual should come first and athletics is purely secondary

Clinical Notes, Suggestions and New Instruments

A NEW SYRINGE FOR THE MULTIPLE SYRINGE METHOD (LINDEMAN)

JAMES SHERMAN HOUCK M D ROCHESTER N Y

Within the last few years many new appliances for blood transfusion have been devised to make the direct transfusion of whole blood safer, simpler and more convenient It seems however that, in spite of these, more physicians and hospitals prefer and employ the Lindeman multiple syringe method I feel that with properly trained assistants this method is the safest for both donor and recipient

How shall the transfusion of whole unmodified blood be done when a patient has an infected blood stream? The possibility of contaminating the donor with the instruments ordinarily used has often been the stumbling block to the use of unmodified blood Realizing that the multiple syringe method removed this hazard, provided each syringe was used but once during the procedure, I developed the syringe as shown in figure 1 It has greatly simplified this method of transfusion because it eliminates the two most important shortcomings of the Lindeman method

1 Difficulties in holding the needle and syringe while withdrawing blood from the donor and injecting it into the recipient

2 Accidental withdrawal of the needle from the vein

The capacity of the syringe is 20 cc The barrel has fastened to it a special thumb rest for comfortably holding the needle and the syringe, also an extra large, solid glass end with metal Luer tip

The bearing surface of the plunger has been shortened to about 1½ inches The other part of the plunger is ground fifteen-thousandths inch smaller This construction hinders any blood that may coagulate on the exposed part of the plunger from interfering with the smooth working of the syringe A description of the technic (patient with infected blood stream) now used entirely at the Genesee Hospital will best illustrate the advantages of the syringe

The recipient's and donor's arms are prepared in the usual manner and their stretchers are arranged with a work stand between them mutually convenient to the operator and his assistant Twelve or more 20 cc. syringes are placed on the work table, the number of syringes to be governed by the amount of blood to be given The operator inserts as large a caliber Unger needle as the recipient's vein will accommodate, either 15 or 16 gage, for children 18 gage, 1 inch of the needle to be within the lumen of the vein, if possible. The index finger should be back of the needle shield, across the needle hub One should press firmly down against the recipient's arm The middle finger is in front of the needle shield opposite the

Fig 1—Improved syringe with special thumb rest.

index finger, resting on the needle cannula, as shown in figure 2 Maintenance of this position throughout the transfusion will actually lock the transfusion needle in position and makes accidental withdrawal of the needle from the vein very difficult. This position further leaves the thumb free either to close the open needle hub when the syringe is removed or to lock the needle and syringe firmly together when administering the blood as illustrated in figures 2 and 3 The needle now being properly fixed in the recipient's vein saline solution is slowly administered while the assistant places a large caliber Unger needle 13 or 15 gage in the donor's vein using the same steps as described for the recipient The blood is drawn into the syringe from the donor and here it will be observed that the thumb rest acts as a counterforce to the pull of the syringe plunger It is this pull that so frequently runs the transfusion by with-

drawing the needle from the vein. As each syringe is filled by the assistant, it is unlocked from the needle by lifting the thumb from the thumb rest and rotating the syringe gently to loosen it from the needle hub. As soon as the syringe is removed, the thumb quickly closes the open end of the needle hub and the filled syringe is laid on the table ready for injection.

Fig. 2—The syringe and needle comfortably held and locked together between the middle finger and the thumb. The thumb rest serves as a counterforce to the pull of the syringe plunger when blood is being withdrawn.

into the recipient by the operator. He administers the blood to the recipient and hands the syringe to the nurse, who immediately takes it apart and washes it. The syringe is not again used during the transfusion and so it is impossible to infect the donor.

Fig. 3—Syringe unlocked from needle operator's thumb about to be placed over hub of needle.

We use this method whenever giving unmodified blood. If the recipient is not infected we use the syringe again and again, ordinarily having six syringes on the work table. The operator administers the blood to the recipient and gives the used syringe to the nurse. She flushes each syringe thoroughly through three basins of physiologic solution of sodium chloride and places

the syringe on the work table convenient to the assistant. We prefer this method as it is adaptable to use in the crowded rooms, where it would be impossible to have the stretchers placed head to head as is necessary with some of the instruments now being used, and further because it means no complicated apparatus. We ordinarily keep our syringes autoclaved in a canvas roll so that we have them ready for use at any time.

I feel that the new syringe construction has greatly simplified the multiple syringe method and hope that it will be the means of making this method still more popular.

THE USE OF LIVING FASCIA TRANSPLANT TO REPAIR A HERNIA OF THE TIBIALIS ANTICUS MUSCLE

JOHN B. HARTZELL, M.D., DETROIT

It was over thirty years ago that McArthur¹ first brought out the use of fascia as a suture in the repair of hernia. After incising the external oblique aponeurosis he cut a small strip off the free border of the medial and lateral flaps. He left these attached at their inferior ends. After ligating the sac he used the strip from the medial border to suture the internal oblique muscle to Poupart's ligament under the cord. He then used the strip from the lateral border to suture together over the cord the flaps of the aponeurosis of the external oblique. Three years later he reported ninety-three consecutive cases in which fascia had been used as a suture without recurrence of the hernia. One of his patients died a year after the operation had been performed and he secured the scar. Microscopic sections showed the graft passing through the scar as living fibrous tissue. Although this work was well received it was to be twenty years before the use of fascia as a suture material was to be brought into more general use.

This came about largely through the experiments of Gallie and LeMesurier.² Working on rabbits and dogs, they found that fascia readily united with fascia, that the strength of the union depended on the area of the surface in contact. They further found that the surfaces placed in contact must be deprived of their sheet of areolar tissue and fat, otherwise the strength of their union is slight. Such surfaces should be thoroughly scraped and scarified in order that when healing does occur the new connective tissue may have a deep grip among the fibers. Three years later these same authors reported 100 abdominal and inguinal hernias repaired by means of fascia lata living suture without a recurrence.

Since that time Koontz,³ Rosenblatt and Cooksey,⁴ Meyers,⁵ Haas,⁶ and Hodgkins⁷ have reported excellent results with living fascia lata as a suture material. Patterson⁸ and Allen⁹ working independently have used living grafts of fascia as a method of internal fixation in fractures and dislocations. Grace,¹⁰ Fuld,¹¹ Masson¹² and Bate¹³ have each devised strippers that simplify the removal of strips of fascia lata.

The use of fascia lata as a transplant in the repair of herma is now a well established surgical procedure. The fact that the use of it is attended by nearly universal success would indicate that this tissue possesses a remarkable vitality. It has been shown that both living and preserved fascia, when used as suture material in suturing fascia to fascia or fascia to muscle, will remain in the tissues and eventually become a part of a dense fibrous union.

REPORT OF CASE

A man, aged 42, while climbing out of a stream four years before fell shin first on top of a sharp stump, receiving a painful bruise. He had paid little attention to his injury after the bruise disappeared. Slowly a large lump developed at the site of the old injury and during the last ten months this lump had become painful, precluding his favorite forms of exercise. The last two months it ached constantly and was made much worse by even a short walk.

Examination revealed a lump about 2 cm in diameter and 1 cm in height. It was situated on the anterior surface of the right leg just proximal to the junction of the middle and lower thirds of the right tibia, over the lower portion of the belly of the tibialis anticus muscle. This lump would appear and disappear with dorsal and plantar flexion of the foot. With each appearance the patient experienced a dull ache. It could not be reduced by pressure and was tender on palpation. The diagnosis was a muscle hernia of the belly of the tibialis anticus. It was thought that the rent in the fascia of the tibialis anticus might be repaired.

Under local anesthesia an incision was made over this swelling. There was a definite fault in the fascia covering the tibialis anticus muscle. This appeared as a definite ring with a diameter of about 2 cm. The muscle bulged through this opening. The fascia was so taut that it was impossible to approximate it. An incision was made lateral to this opening. An attempt was made to slide the fascia medially in order to obliterate this space. The fascia was so taut that this could not be done. Even under marked tension it could be moved barely half a centimeter. It was decided that the only means of obliterating this opening was by the use of a fascia transplant. A strip of fascia lata about 10 cm long and 1 cm wide was then removed from the left thigh. This incision was closed with interrupted chromic sutures. This piece of fascia was split into three strips each about one-third centimeter in diameter. These strips were then woven in basket pattern into the opening. The ends were carried well into the fascia bordering the opening and anchored firmly in place. The skin was closed with interrupted dermal sutures. The foot and leg were placed in a posterior plaster splint. The skin was under so much tension, owing to the increased thickness of the tissues resulting from this woven fascia graft, that the skin stitches cut through and were removed on the fifth day. The skin margins separated and the fascia graft was plainly visible. As in any open wound a small amount of purulent secretion accumulated on it daily. Moist boric acid dressings were applied. By the tenth day definite granulations appeared to be budding up between the strips of fascia. It is a well recognized fact that the wounds in this area are frequently very slow in healing owing to the poor blood supply. This case was no exception. The granulation tissue filled in slowly until it covered the fascial graft. The wound then gradually epithelized. At present it is over a year since the operation. There is a dense scar with no protrusion of the muscle.

COMMENT

Here is an example of a good result in a transplant of fascia lata into an area in which the blood supply is notoriously poor. The wound could not heal by first intention owing to the fact that a skin separation occurred because of tension. The wound then healed by granulation. The granulation tissue grew up between the grafts and then over them. Definite buds of granulation tissue became firmly attached to the fascial grafts until finally the grafts were completely covered. At no time did any of the fascial sutures show any disposition to slough.

We have been unable to find any reference to another case of hernia of the tibialis anticus muscle. We believe that this is the first time that such a hernia has been repaired by a living fascial graft and that the healing process has been observed grossly from day to day during the period of repair.

7815 Jefferson Avenue, East.

AGRANULOCYTIC LEUKOPENIA INDUCED BY A
DRUG RELATED TO AMINOPYRINE

JULIEN E. BENJAMIN, M.D. AND JOSEPH B. BIEDERMAN, M.D.
CINCINNATI

In a previous communication we¹ reported a clinical study of a patient who developed agranulocytic leukopenia after ingestion of aminopyrine but who was able to take other related drugs with no deleterious effect. The patient has been well since the latter part of April 1934.

Recently there has been brought to our attention a drug chemically related to aminopyrine and supposedly less toxic, known as "Novaldin,"² which is sodium phenyldimethylpyrazolon methylaminomethane sulfonate. The following procedure was carried out in an effort to appraise the virtue of this drug.

The same martyr who volunteered herself for previous experimentation is a nurse, aged 50. She had had several attacks of agranulocytic leukopenia due as we have proved, to the ingestion of aminopyrine. Since discontinuing its use, she has had no recurrence. Her white blood count Feb 12, 1936, was 5,300. The differential count was polymorphonuclears 69 per cent, lymphocytes 25 per cent, transitionals 4 per cent, large mononuclears 1 per cent, eosinophils 1 per cent. Immediately after the blood count was taken she was given 10 grains (0.65 Gm.) of Novaldin. At 3 p.m., exactly three hours after ingestion, another blood count revealed white blood cells 5,200, polymorphonuclears 72 per cent, lymphocytes 20 per cent, large mononuclears 6 per cent, transitionals 2 per cent, as

shown in the chart. At 8 p.m. the patient felt chilly and tired. She went to bed with a slight headache. This pain increased to such an extent that at 3 a.m. it was severe enough to awaken her. At that time her feeling of fatigue was greatly increased. At 5:30 a.m. she felt hot, took her temperature, and found it to be 99.4 F. At that time her headache was severe and backache developed. The symptoms persisted for twenty-four hours after ingestion of Novaldin. Blood examination revealed the following: The white blood count was 2,800, polymorphonuclears 46 per cent, lymphocytes 43 per cent, large mononuclears 6 per cent, transitionals 5 per cent. Her physical examination at this time revealed nothing abnormal.

February 14, forty-eight hours after taking the drug, she felt much better, but a slight headache still persisted. The blood examination revealed a tendency to return to the normal. The total white count was 4,100, polymorphonuclears 46 per cent, lymphocytes 48 per cent, large mononuclears 2 per cent, transitionals 4 per cent.

Seventy-two hours after the initial dose of Novaldin she had recovered. The white blood count was 4,800, polymorphonuclears 54 per cent, lymphocytes 40 per cent, large mononuclears 4 per cent, eosinophils 2 per cent.

February 16, four days after she took the drug, she complained of a headache. Her white blood count was 4,000, polymorphonuclears 51 per cent, lymphocytes 40 per cent, large mononuclears 6 per cent, transitionals 3 per cent.

1 Benjamin J. E. and Biederman J. B. Agranulocytic Leukopenia J. A. M. A. 103: 161-163 (July 21) 1934.
2 Winthrop Chemical Company

February 17, five days after ingestion of Novaldin, she felt perfectly normal. Her white blood count was 5,000, polymorphonuclears 55 per cent, lymphocytes 39 per cent, large mononuclears 3 per cent, transitionals 2 per cent, eosinophils 1 per cent.

February 19, one week later, she felt fine. The white count was again 5,200, polymorphonuclears 69 per cent, lymphocytes 26 per cent, large mononuclears 2 per cent, transitionals 2 per cent, eosinophils 1 per cent.

ALLERGY TESTS

An intracutaneous skin test with Novaldin was negative. A patch test with the drug also was negative. A passive transfer test was then performed, 0.1 cc. of the patient's serum being injected into the skin of a normal person. This was followed forty-eight hours later by the injection into this site on the normal subject of a test solution of Novaldin. No reaction resulted, indicating the absence of reagins for Novaldin in the blood of the patient.

SUMMARY

1 A case of granulopenia resulted from the ingestion of Novaldin.

2 During a period of good health the patient was given 10 grains (0.65 Gm.) of Novaldin under control. This produced symptomatic signs of agranulopenia within eight hours and objective signs (blood examination) within twenty-four hours.

3 Intracutaneous, patch and passive transfer tests gave negative reactions.

4 In this patient the effect of Novaldin was one of hypersensitivity to the drug with the hematopoietic system acting as the shock organ.

5 Seventy-two hours after the drug had been taken, a normal state of health was restored.

CONCLUSION

"Novaldin," a drug related to aminopyrine, is capable of exercising the same deleterious effects as aminopyrine on the hematopoietic system.

19 West Eighth Street.

INFANTILE ECZEMA FROM COD LIVER OIL

REPORT OF TWO CASES

SAMUEL J. HOFFMAN, M.D. AND HERBERT RATTNER, M.D.
CHICAGO

Cod liver oil is not usually considered a possible cause of eczema in infants. For that reason two such cases are herewith reported.

The first baby, a boy aged 22 months had eczema rather generalized, the patches being more acute in the cubital and popliteal spaces and on the face and neck. The eczema first appeared on the day the baby came home from the hospital, after birth, and had persisted with remissions and exacerbations since then. The child's birth was normal and the period in the nursery was uneventful. On his first day at home he was given cod liver oil with viosterol in addition to the breast feeding. The eczema then appeared and became gradually more severe. The diet was changed from time to time and the usual topical remedies were employed, but it was never considered that the cod liver oil might be the source of the eczema. In general the child was in good health, of normal weight and with a general healthy appearance despite the fact that he presented a feeding problem and vomited regularly. At nine months of age when he was given solid foods fish was one day included in the diet and produced in the child severe urticaria and vomiting. The attack was transitory, the fact that he was getting cod liver oil escaped attention, and the eczema persisted in a chronic state. He was never entirely free from it. One day recently the child walked into the kitchen where fish was being fried. He immediately developed severe giant hives, conjunctivitis and exacerbation of the eczema apparently from inhalation for the child had not been fed any of the fish. Then and not until then did he awake to the fact that cod liver oil might be the source of the child's eczema. It was omitted and within forty-eight hours the skin showed a very decided improvement, gradually to clear up entirely. The vomiting has

stopped, he is no longer a finicky eater, he has gained in weight and the general state is excellent. Viosterol in oil was substituted and he seems to tolerate it well. On one occasion later, when he was accidentally exposed to fish odors, there was an immediate recurrence of urticaria and conjunctivitis.

The second baby, a girl aged 18 months, presented an acute eczema of the face, scalp and trunk and the cubital and popliteal spaces, of four months' duration. It was learned that at about that time cod liver oil had been fed to the child for the first time. It was discontinued, with skepticism on the part of the parents, and the eczema disappeared completely, to recur after a trial feeding with cod liver oil. This child, too, had a recurrence from inhalation when fish was being cooked in the home.

In both cases the fathers of the children were sufferers from seasonal hay fever.

It has long been recognized that there are individuals who are sensitive to fish, and there have been numerous cases in which untoward reactions have occurred, usually in the skin as urticaria, in the gastro-intestinal tract, and in the respiratory tract. Unusual cases are frequently encountered. Rowe¹ cites instances from the literature in which alarming reactions followed the licking of a postage stamp, and in one patient after wearing shoes in which inner soles were glued, the glue in each case being made from fish. Glue is used frequently on toys, especially on dolls with hair. It may be that cases are not infrequently missed because these unusual sources are not thought of or because, as was the case with one mother, she just hadn't thought of cod liver oil as fish.

University of Illinois College of Medicine

Special Clinical Article

PRESENT STATUS OF TRANSURETHRAL RESECTION OF PROSTATE

CLINICAL LECTURE AT KANSAS CITY SESSION

H. C. BUMPUS, JR., M.D.
PASADENA, CALIF.

The relief of urinary obstruction resulting from prostatic enlargement by transurethral resection has freed the mind of the aging man of one of his chief worries, seeming to assure many of the possibility of a happier senescence than could have been expected formerly. In fact, during the past few years, wherever a group of elderly men has gathered, it has not been unusual to hear expounded the advantages of the new so-called electric operation over the former cutting operation for the relief of prostatic obstruction. While the minds of the laity have become filled with a feeling of confidence, those of the profession have become more and more confused by the diversity of reports concerning the results of transurethral resection appearing in medical literature. For many years the general practitioner has listened to his urologic brethren extol the merits of the suprapubic or perineal operation, always interested in their discussions, he has invariably based his opinion regarding the relative merits of the two operations on the clinical results that have come under his observation. In the past few years he has found his medical literature and scientific programs again filled with conflicting reports concerning the efficacy of still another form of treatment for the relief of prostatic obstruction. He reads that at the Mayo Clinic in 1935, 695 patients with prostatic obstruction were treated by transurethral resection with but seven

Read in the General Scientific Meetings at the Fishy Seventh Annual Session of the American Medical Association, Kansas City, Mo., July 11, 1936.

deaths, a mortality rate of approximately 1 per cent. In less than a week 58 per cent of those patients had left the hospital, while at the end of two weeks 28.7 per cent more had been discharged, making a total of 86.7 per cent who had two weeks or less of hospital expense associated with their operation. He contrasts these results with those occurring at the same institution following suprapubic prostatectomy. After the latter operation the mortality rate in any single year was seldom below 6 per cent and not infrequently rose to over twice that figure, while the majority of patients were compelled to remain over a month in the hospital. The superior results following resection he might attribute to the advantages of cooperative endeavor in an institution such as the Mayo Clinic had he not learned that T. M. Davis,¹ who first popularized the method, had performed resection on 966 patients with a loss of but seven. Dr. Davis also reports an average postoperative hospitalization of but eleven days for his patients.

Such results naturally arouse not only admiration but a sincere effort at imitation. It is this effort to emulate the success of the pioneers that I believe is responsible in a large measure for the confusion that now exists in the minds of the profession regarding the relative merits of the procedure, for all too frequently surgeons with insufficient experience undertake the procedure, not appreciating what potential danger lurks in the few centimeters comprising the prostatic urethra. It has a rich blood supply, so that any trauma not only is likely to be followed by brisk bleeding but will afford a direct entrance into the blood stream for whatever organisms may be present in the prostatic ducts and gland acini. Those who have never witnessed a so-called urethral chill with its profound prostration, elevated temperature and general collapse little appreciate how serious can be the consequences of any surgical procedure in this location.

Owing to the extreme technical skill required in its performance, the opportunity to learn the technic of transurethral resection in any series of cases sufficiently large to insure an adequate degree of skill is exceedingly limited. Because the entire operation is performed through a channel as limited as the urethra, the instruction of others in the intricate steps of the procedure is difficult. In fact, it is a procedure the technic of which can be satisfactorily mastered only by actual performance, since reading and personal instruction give but little help.

The few institutions where opportunity for developing such technic is available are large county hospitals, so it is not surprising that the inquisitive physician finds that in one of the country's largest hospitals, namely, the Los Angeles County General, following 154 transurethral resections there were nineteen deaths, a mortality of 11.2 per cent, and in an equal number of cases a second resection was required. In fifteen of these cases the bleeding following resection was so excessive as to demand operative intervention. If results of this kind are to be expected in large, well organized urologic services, how much more deplorable must they be in small hospitals where only occasional cases are available for treatment and where the general practitioner in observing the functional results of prostatic resection is likely to see not the result of a trained operator's skill but the unforeseen complications of a novice's work and

so look on the operation unfavorably. In other words, he will condemn the operation when in truth he should censure the operator, consequently, in any community where the profession is acquiring this experience, the procedure is more likely to be regarded unfavorably than favorably. This is exemplified by a questionnaire recently completed by Orr. He found that five urologists, all of whom had operated in more than 500 cases, reported a mortality rate of 1.9 per cent for the 4,767 cases in which they had operated, while twenty-five others who had done between 100 and 200 reported a mortality rate of 4.1 per cent for their 3,530 cases. Alcock,² who had performed over 1,500 resections, lost fifteen of his first 100 patients, while in his last 500 the mortality rate was 1.4 per cent, although the average age of these 500 patients was over 70 years. My own experience is similar. Eight deaths occurred during my first 250 cases, followed by over 300 cases before the next mortality occurred. Davis reports having lost but two patients in his last 500 cases. It is evident that in the hands of the experienced the mortality rate should be less than 2 per cent. In fact, it must be considerably lower than that associated with other forms of treatment if it is to replace them.

PREOPERATIVE PREPARATION

Its lower mortality by no means constitutes the only advantage of the procedure. Formerly the emphasis in these cases of prostatism was placed so strongly on the preoperative preparation that many urologists considered it far more important than the operation itself, and the preparation of patients for prostatectomy frequently required an extended period of time in order to render them in sufficiently good physical condition to undergo the ordeal. Much of this preparation consisted in the removal of the residual urine either by intermittent catheterization or by continuous catheter drainage. Prostatic resection being a much less drastic procedure, patients in much poorer physical condition can successfully undertake it, for once the obstructing portion of the prostate is completely removed, the menace of residual urine is abolished, consequently, in the comparatively short time consumed in the operation there is accomplished what formerly required the use of a catheter for many days and sometimes many weeks.

Now the emphasis is entirely shifted. Thompson³ at the Mayo Clinic reports that 65.7 per cent of the 695 patients who had resection there during 1935 received no preliminary treatment whatever. This in itself is a tremendous saving to the patient when one recalls the weeks of hospital care not infrequently deemed necessary prior to prostatectomy.

It is not to be wondered at, therefore, that laymen are expressing a decided preference for this newer procedure with its lessened expense as a result of shorter hospitalization, to say nothing of its negligible mortality rate. That the profession is not equally enthusiastic demands explanation, for in many communities the procedure was at first accepted without question as a decided advance, while now it is referred to with the utmost skepticism. In examining figures such as those compiled by Dr. Negley,⁴ the reason for this becomes apparent. From Jan. 1, 1934, to Jan. 1, 1935, 251 patients were operated on in five different hospitals in the Los Angeles district with a mortality

² Alcock, N. G. Prostatic Hypertrophy. *J. A. M. A.* 104: 734-738 (March 2) 1935.

³ Thompson, G. J. Personal communication to the author.

⁴ Negley, J. C. Personal communication to the author.

¹ Davis, T. M. Personal communication to the author.

rate of 87 per cent and an average hospital stay of thirty-four days. Obviously the results in the resection cases were not a great enough improvement to call forth much enthusiasm for the method. Indeed, such statistics, when compared with those of more experienced operators referred to earlier in the paper, demonstrate that the surgeon lacking such training will do better to perform a prostatectomy.

POSTOPERATIVE TREATMENT

While formerly the preoperative preparation of patients contemplating prostatectomy was generally accepted as the most important and usually the most tedious portion of their treatment in the case of resection, it is now the postoperative management, and the most meticulous observation of the minutest detail becomes imperative.

After most operative procedures the surgeon leaves the hospital with the knowledge that the house staff and the nurses will adequately take care of the usual complications occurring during convalescence and that the satisfactory progress of his case depends largely on the patient's general resistance. Such is not the case with the patient who has just undergone resection. His general condition may be of the best, but let the drainage tube become occluded for only a short period of time and the complications that may occur are legion. And it is easy for the drainage tube to become occluded: it may become kinked, a small clot may obstruct it, the catheter may have been badly adjusted following operation, the patient may roll over on the tubing for a short time, a nurse may forget to fill the irrigating reservoir and as a result air bubbles obstruct the system, or, having clamped off the tubing while she empties the receptacle, she may forget to unclamp it after returning the urinal. Such obstruction may result in so great an overdistention of the bladder that the operative field is stretched and torn and serious bleeding develops, but more often it initiates a febrile attack. To prevent such reactions, not only must the outflow of urine be continuous and unobstructed but the greatest care is necessary to see that no organisms foreign to the host are introduced into the urinary tract. This cannot be accomplished if the nursing force permits the drainage tubes to lie on linen soiled by anal contamination or tucks them between mattress and sheet while emptying the receptacles. Strange as it may seem, the amount of indifference to aseptic technic following operation usually exceeds the amount of care given to the punctilious performance of its smallest detail in the operating room. To insert a sterile catheter in the bladder and then order that it be irrigated by the floor nursing staff every ten minutes for the first two or three hours after operation is to believe that the boundaries of aseptic technic are as far flung as those of the stratosphere while to permit the catheter to drain into an occasionally sterilized urinary receptacle is to insure the early contamination of the operative field and the unnecessary prolongation of convalescence.

Bacteria pass up tubing into the bladder from any point of contamination, so that if an aseptic technic is to be followed after the operation it is best to attach the catheter to a closed system and if possible never open it except with the most rigid aseptic precautions. This can be done by attaching a reservoir to the tubing that leads from catheter to urinary receptacle. If need be, the bladder can be irrigated by allowing the fluid (which

may be germicidal if desired) to flow in through a T tube. The receptacle that collects the urine should be sterile and instead of being emptied when filled should be replaced by a similar sterile receptacle. Otherwise it is impossible to keep the urinary tract free from secondary infection and the receptacle clean.

When enough resections are being done in a hospital to insure a nursing staff being specially trained and always available for their care, attention to these details is easily accomplished and the advantages of the newer method of treatment speak for themselves and need no press agent. But in hospitals where only an occasional case is handled and where surgery of the urinary tract represents but a small minority of the surgical work, this attention to detail seems impossible, and without it postoperative complications will be so frequent and annoying that this method of treatment comes rapidly into disfavor, not alone among those who attempt its performance but among the other members of the staff who are eager to evaluate any new procedure. If to this is added the lack of technical skill of any one who has not done at least a hundred of these operations, the unpopularity of the procedure in certain localities is not hard to understand.

COMPLICATIONS

Discouraging as these occurrences can be, bleeding is undoubtedly the complication that has most frequently brought ill repute to the procedure. In fact, for over a hundred years this complication has kept the method from general adoption, for the attempts to remove the obstructing prostatic tissue transurethrally are not new, only their successful accomplishment is recent. In 1840 Mercier was removing tissue through an instrument not unlike many in use today, but he had no way of controlling bleeding, and when Dr. Young presented his punch instrument before the International Urological Congress in 1909 he advised that its use be confined to minor obstruction, for there was no way to control hemorrhage resulting from more extensive removal of tissue.

With the application of the various types of electric currents to medical use the control of bleeding becomes possible, so that today it occurs as a complication in the hands of the experienced in probably less than 5 per cent of the cases, and in these seldom in a serious form. If a patient bleeds after suprapubic prostatectomy there is always a suprapubic opening through which the clots may be exuded and pressure relieved, not so in the resection case. If the catheter or urethra becomes obstructed by even a small clot, when the bladder fills it will contract in an attempt to expel it, ineffectual spasms of the bladder musculature will develop, and the bleeding, which was insignificant to start with, becomes aggravated. More clots form, which the bladder tries vainly to expel, and so a vicious circle is established. There is nothing to be gained by watchful waiting in the hope that the bleeding will stop. Although many novices in the care of these patients have this hope or else attempt to remove the clots by dilution, forcing more fluid into an already distended viscus (a practice that can result in vesical rupture, and is to be condemned), bleeding will continue until the bladder has been cleared of clots. To the experienced the evacuation of clots from a distended bladder is not a serious or difficult procedure. It is seldom that the vessel which is bleeding is of sufficient size to result in a loss of blood dangerous to the patient's life, far more fre-

quently obstruction caused by the resulting clots, rather than hemorrhage, is the difficulty to be met. Clots in the bladder can be evacuated with proper instruments in a very few minutes, and the bleeding vessel, if still active, can be readily stopped by coagulation. Usually on evacuation of the clots the bleeding stops spontaneously. To the inexperienced, bleeding is a formidable and serious matter and is likely to occur rather frequently, necessitating transfusions and even cystotomy. The stopping of such bleeding by transurethral methods requires the maximum of technical skill, and those who have not attained such skill will choose the method of opening the bladder suprapubically for the evacuation of clots. To have informed a patient of the benign nature of transurethral resection and, having undertaken it, to be compelled after an ineffectual attempt to control an attack of postoperative bleeding to do a suprapubic cystotomy is likely to cool the ardor of the most enthusiastic resectionist who lacks training. Like the poor carpenter, such an unfortunate is inclined to blame his tools and decide that he has chosen the wrong instrument for his work.

INSTRUMENTS

That three different instruments and technics are usually employed for the transurethral removal of tissue and the control of bleeding has certainly added to the general confusion regarding the efficacy of the procedure. Where many remedies are recommended, the inexperienced are inclined to believe that not one is satisfactory. Some workers, preferring to use the original principle of Dr. Young, excise the tissue with a tubular knife as it is caught in the fenestrum of the hollow tube. To control the bleeding they depend on the local application of the coagulating current to the surface after the tissue is excised. The advantage of this method, they maintain, is that the coagulation and hence the destruction of tissue is kept at a minimum, insuring the more rapid healing that occurs in the case of an incised area as compared to a charred or coagulated one. Thus a more rapid and painless convalescence may be expected. The instrument seems to have the added advantage that it does not easily injure the external sphincter and is less likely to remove tissue beyond the borders of the gland, so that the possibilities of incontinence and extravasation of urine are lessened. In the hands of the inexperienced it seems the least dangerous of the three types of resectoscopes now in general use. However, its employment necessitates a familiarity with the direct cystoscope, an instrument with the use of which the majority of urologists are not familiar, most of them having confined their experience to the employment of lens instruments, a regrettable technical limitation but one that has prevented the general adoption of this method of transurethral resection.

Most urologists prefer to use a lens instrument with a reciprocating wire loop originated by Stern and perfected by McCarthy. This loop is activated by a high frequency current which excises the tissue and through which a coagulating current passes for the control of bleeding. Because the operation is observed through a lens system it is imperative that the field of vision be at all times as clear as possible, to insure which the coagulation of bleeding vessels must be carefully carried

out. Add to the coagulation necessary to excise the tissue that which is necessary to insure adequate vision, and the aggregate result is a rather extensive charred area the healing of which is bound to be prolonged. The loop electrode is also dangerous in that, being pulled toward the operator, it can very easily, in the hands of the inexperienced, injure the external sphincter and result in a urinary incontinence (a complication that should be charged against the operator and not against the operation). The same statement of course applies to the postoperative strictures that have been reported following resection. They are the natural result of unnecessary trauma to the urethra brought on by the passage of too large an instrument or a too prolonged operation at the hands of the inexperienced. Their occurrence cannot justly be attributed to the operative procedure.

The third most popular method of resection is that developed by John Caulk, who uses a combination of the two previous ones, excising the tissue with a tubular shaft the end of which has been transformed into an actual cautery. He believes that such cauterization is less penetrating than that produced by the high frequency current, and that tissue destruction is therefore less, and healing more rapid.

APPLICABILITY OF TRANSURETHRAL RESECTION

Because of the untoward results of too extensive cauterization, many urologists have advocated the limitation of the procedure to the smaller type of median lobe hypertrophy and contracted bladder necks. Until prostatic resection became popular, few had interested themselves in the amount of tissue that was usually removed at prostatectomy. It was known that the average normal gland weighed about 23 Gm and that hypertrophied ones had been removed weighing over 200 Gm, but what the average amount of tissue excised at an operation was had not been determined. I weighed the tissue removed in 575 consecutive suprapubic prostatectomies done at the Mayo Clinic and found only 32.1 per cent to weigh more than 50 Gm, while Alcock found the average weight of 433 he had removed to be 38.3 Gm. He tritely remarks, "If with the resectoscope one removes from 15 to 35 grams, one is removing a very large part of the average gland." As the removal of such an amount of tissue is readily accomplished in less than an hour's time, the new procedure seems well suited for the majority of men suffering from prostatism. The huge glands that are suitable for museum collections will of course require other procedures for their removal, unless the patient is willing to have or prefers multiple resections in place of prostatectomy.

The incidence of multiple resections is frequently inquired into by those interested in the method and not infrequently caustically referred to by its critics. Although it is usually possible to complete a resection at one time, it is not always desirable as postoperative reactions seem to bear a direct relationship to the time consumed in the operation. There are several reasons for this. The urethra always resents undue trauma, and the importance of gentleness in the passage of instruments through it remains unchanged. In transurethral work these instruments are of larger caliber and remain in the urethra for long periods of time, so

that injury to the mucosa by the continual pressure can readily occur. Because the instruments are of large caliber, care should be exercised to see that the urethra is adequately dilated by the passage of sounds before their insertion. Too often at the present time one may see the enthusiastic resectionist forcing an instrument several sizes too large for the caliber of the urethra. Such manipulation is likely to result in periurethral abscesses, fistulas or strictures. To relieve the patient of a urinary obstruction due to prostatic hypertrophy and as a result leave him with obstruction due to urethral stricture is inexcusable but can be avoided only by careful procedure. A multiple stage resection is far preferable to such an outcome, and when its necessity is explained to patients few offer objection, realizing that to repeat a procedure as little debilitating as a resection is preferable to spending the time in the hospital required by prostatectomy.

There is no question that the operation of resection is difficult and when undertaken in the case of large hypertrophies is tedious in the extreme to the operator, while a prostatectomy is an easy operation for the operator but carries a much greater risk for the patient. Surgeons are human, and, other things being equal, some are inclined not only to select the easiest procedure but sure to resent the popularity of any method the adoption of which is difficult or impossible for them to master individually. Such members of the profession are heard to say "Yes, it is an excellent procedure when properly applied. Its field, however, should be limited to the lesser types of obstruction and to the poor types of risk, such as patients of advanced age with marked physical impairment brought on by their failing cardiovascular renal systems." If a procedure is safer for the greatly debilitated, it must of necessity be safer for the normal, and it is difficult to understand how a procedure that is admittedly more dangerous can be recommended simply because it is easier for the operator. Twinem recently reported the total operative mortality since 1920 for the thirty-three patients over 80 treated by prostatectomy either suprapubically or perineally at James Buchanan Brady Foundation of the New York Hospital as 33½ per cent, while Alcock reports doing resections on 124 patients over 80 with an 11.3 per cent mortality, and Thompson at the Mayo Clinic performed resections on thirty-eight patients over 80 during 1935 without a death.

Every urologist who performs a large series of resection operations is sure to fall heir to a number of patients whose advanced age has made other members of the profession hesitate to operate by the older methods. In fact, the first cases that the pioneers in the procedure handled were those that they or their associates feared to risk submitting to a prostatectomy.

RECURRENTS

Will this newer operative procedure be as permanent as the older methods? is a question frequently confronting its advocates. More time must elapse before this can be answered with authority. It is going to be difficult to distinguish, in an acute survey, those cases that constitute a true recurrence from those in which a return of the obstructive symptoms occurs because of the initial incompleteness of the first resection. At the present time the number of patients returning for a

subsequent resection after a prolonged period of relief appears to be less than the number who succumbed following the older methods of removal. Those that are so unfortunate as to require such a subsequent resection have, in my experience, felt that a repetition of the procedure was preferable to the risk involved in the more drastic enucleation.

Hugh Cabot⁵ has recently written

"The real nub of the question turns upon the decision as to who is to treat by operation these people with obstructing prostates. If they are to be treated in the future as in the past, largely by the general and perhaps occasional surgeon, then the indications are for an operative method as nearly fool proof as may be. But this does not seem a high ideal for surgical practice. If it is the standard that we are to accept, then we must take it with the mortality, which in this country at least has rarely been below 15 per cent or even 20 per cent. That any elderly man is likely to shy at such a risk will be evident. If these men are to be treated by experts, then transurethral resection can already claim over 5,000 such cases carefully observed in which the mortality rate has been below 2 per cent and the hospital confinement has been less than a week, with functional results the equal if not superior to those obtained by the older methods."

What the profession chooses for itself is usually an excellent indication of what the public will ultimately demand. Ten per cent of my last hundred patients who had prostatic resection have been physicians.

112 North Madison Avenue.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER Secretary

HEALTH RAY SUN LAMP NOT ACCEPTABLE

Manufacturer Health Ray Manufacturing Company, Inc., New York

The Health Ray Sun Lamp consists of an arc between carbon electrodes operated in a metal housing 8½ by 8½ by 4½ inches in outside dimensions.

The front side of this metal box is covered with a small mesh wire screen, through which the arc radiation emanates. The rear side of the box consists of a hinged door, on the inside of which is mounted a porcelain insulating base that supports the carbon arc electrodes and the ballast resistance. The housing is mounted on a yoke that permits adjustment in the vertical plane.

The carbon electrodes are held in a vertical position, side by side, but separated about one-half inch. The arc is formed by bringing the upper ends of the electrodes in contact, by rotating the support of one of the carbon electrodes, which support terminates in a hard-rubber knob, on the outside of the door. After the arc has been operated for several minutes this knob becomes uncomfortably hot, and hence it is difficult to adjust the arc.

The housing, being single walled and so small, becomes burning hot to the touch after the arc has been operated for from five to ten minutes. While the housing did not become sufficiently hot to burn bits of paper placed on it and hence is probably not a fire hazard, nevertheless it cannot be recommended for treating children unless guarded by an attendant.

Instead of supplying the purchaser with safety glasses (goggles) to shut out the ultraviolet and yet enable the user to move about in safety, opaque eye covers are provided. These covers of sponge rubber 8 mm in thickness, are cut to fit the

⁵ Cabot Hugh. *Modern Urology* ed 3 Philadelphia: Lea & Febiger vol 1 section 14 chapter 18.

eye socket, viz., 4.5 cm long and 2.5 cm in its widest dimension. This is to be tied over the eyes by means of rubber elastic string. This form of economy (sacrificing safety to cheapen a commodity) is not to be recommended.

ADVERTISING MATTER

In lay advertising, exaggerated or misleading statements have appeared, for example, "Build up your resistance and vitality so that your system will easily throw off germs and poisons," "The Cheapest Form of Health Insurance," and "Improves your appearance 100%." The promoters of the carbon arc Health Ray Sun Lamp place great emphasis on producing a tan. The carbon electrodes supplied with the Health Ray Sun Lamp are "Sun Tan," "Super Tan" carbons that are strong in ultraviolet radiation of wavelength shorter than 2,900 angstroms, not found in sunlight.

RADIOMETRIC TESTS

Following the recommended procedure, by means of a balanced thermopile and filter radiometer, measurements of the ultraviolet radiant flux, of wavelengths shorter than and including 3,132 angstroms, were made at a distance of 24 inches in front of the lamp, which, as already mentioned is covered with a wire mesh screen.

The arc of super tan (sun tan) carbons was operated on 115 volts alternating current, and it burned the quietest on 80 to 85 amperes, the total power input being from 850 to 900 watts.

At a distance of 24 inches the ultraviolet flux (intensity) of wavelengths shorter than and including 3,132 angstroms, with only the wire mesh in place, was 48 microwatts per square centimeter ($\mu\text{W}/\text{cm}^2$), whereas for acceptance as a therapeutic lamp (using C carbons) the minimum is about 55 $\mu\text{W}/\text{cm}^2$.

However, to be acceptable as a sunlamp for home use without the supervision of a physician, the Council specifies that the source shall not emit an appreciable amount of ultraviolet radiation of wavelengths shorter than 2,800 angstroms. In the carbon arc lamps this is accomplished by using a window of Corex-D glass in front of the arc. On this basis the ultraviolet radiant flux of wavelengths 2,900 to 3,132 angstroms is reduced from 48 $\mu\text{W}/\text{cm}^2$ to 9.2 $\mu\text{W}/\text{cm}^2$. This is only about one tenth the intensity required for acceptance by the Council.

In view of the objectionable advertising matter and the weak intensity of the ultraviolet radiation of this generator, the Council voted not to include the Health Ray Sun Lamp in its list of accepted devices.

OTOFLEX NOT ACCEPTABLE

Manufacturer The Otofex Corporation, Milwaukee.

The Otofex is a device for generating tones which are audible within the ordinary sound range. These tones are generated by an electric oscillator making use of vacuum tubes. The frequency of the tones may be changed at will and the volume increased or decreased. An electric motor provides a method whereby the tone may be automatically varied from very low to very high pitch. The tone produced is not unlike that of a siren on a fire truck, but greatly reduced in intensity. The sound is applied to the ear by means of telephone receivers. Additional head-sets may be obtained and each is provided with its own rheostat to govern the intensity. The unit operates on 110 volts alternating current and weighs about 25 pounds.

The device was tested in a clinic acceptable to the Council. In this investigation thirty-one persons were treated: twenty-one women and ten men. Their ages ranged from 21 to 68 years. All had been hard of hearing for a long time and their deafness was truly "chronic." Those who presented themselves were given careful clinical diagnostic examination including tests with an audiometer in a sound proof room. The audiometric tests were repeated approximately every two weeks during the course of treatments. All hearing tests were made by the same person to insure uniformity of method. The sponsors of the instrument suggested that it would be at least a month before the treatments would produce any measurable change.

The users were instructed to sit quietly and listen to the tones for thirty minutes each day. Each one was instructed not to make the sounds extremely loud but to keep them distinctly audible. (It is well known that loud noises may damage the hearing mechanism but it has not been demonstrated that faint or distinctly audible sounds have any deleterious effect on hearing.) At the end of the first month, those who desired to continue were invited to do so. Twenty of the thirty-one used the instrument for twenty-five treatments or more, seven had fifty or more, and five had seventy or more. One used the instrument ninety-four times between Jan 17 and July 25, 1935. More than a thousand treatments were given.

The results of the investigation submitted were not convincing, since no significant changes in hearing were noted, either for the better or for the worse. In the opinion of the Council, the corresponding changes in hearing would have been noted if the patients had not used the instrument at all.

Unless the deafness treated should be of a different nature from that encountered by those who volunteered for study, the Council can see no reason to expect the use of the Otofex to result in any improvement in hearing. In the opinion of the Council, more critical evidence than that received to date would have to be presented.

In view of the negative results of the investigation, the Council on Physical Therapy voted not to include the Otofex in its list of accepted devices.

Council on Pharmacy and Chemistry

ANTIPNEUMOCOCCIC SERUM TYPES I AND II CONTAINING HETEROPHILE ANTIBODIES-LILLY NOT ACCEPTABLE FOR N N R

IN THE REPORT OF THE ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY FOR 1935 IT WAS NOTED THAT A PHARMACEUTICAL HOUSE IS MARKETING AN ANTIPNEUMOCOCCIC SERUM WITH THE CLAIM THAT THE PRODUCT CONTAINS CERTAIN HETEROPHILE UNITS AND NEUTRALIZING AGENTS WITH THE CLAIM THAT THESE REPRESENT ADVANTAGES OVER ORDINARY PRODUCTS OF THIS CLASS. THE FIRM HAS NOT PRESENTED THE PRODUCT FOR INCLUSION IN NEW AND NONOFFICIAL REMOIES. THE COUNCIL VOTED THAT THE FIRM IN QUESTION BE INVITED TO PRESENT THE AVAILABLE EVIDENCE IN ORDER THAT THE COUNCIL MAY CONSIDER IT AND REPORT TO THE PROFESSION OF THE STATUS OF SUCH A PRODUCT IN THE LIGHT OF THE EVIDENCE FOR THE CLAIMS MADE.

THIS ACTION WAS INSTITUTE AND THE FIRM ELI LILLY AND COMPANY SUBMITTED ITS EVIDENCE AND RATIONALE FOR PROMOTION OF THE PRODUCT. FOR THE PURPOSE OF DETERMINING THE PRESENT STATUS OF THIS PREPARATION THE COUNCIL REQUESTED DR. NORMAN PLUMMER (INSTRUCTOR IN CLINICAL MEDICINE CORNELL UNIVERSITY MEDICAL COLLEGE) TO MAKE A REPORT ON THE ACQUISITION OF THESE IMMUNE FACTORS TO ANTIPNEUMOCOCCIC SERUM.

THE COUNCIL HAS APPROVED AND ADOPTED THE FOLLOWING REPORT OF DR. NORMAN PLUMMER ON THE USE OF HETEROPHILE ANTIBODIES IN THE TREATMENT OF PNEUMONIA. THE COUNCIL HAS FURTHER DECLARED ANTIPNEUMOCOCCIC SERUM TYPES I AND II CONTAINING HETEROPHILE ANTIBODIES MARKETING BY ELI LILLY AND CO. UNACCEPTABLE FOR INCLUSION IN NEW AND NONOFFICIAL REMOIES BECAUSE OF LACK OF EVIDENCE OF ITS THERAPEUTIC VALUE. THE COUNCIL DESIRES TO EMPHASIZE THE CONCLUSION OF DR. PLUMMER THAT IN THE LIGHT OF PRESENT KNOWLEDGE RECOMMENDATION OF THE COMBINED HETEROPHILE SERUM FOR GENERAL DISTRIBUTION IS UNWISE AND UNWARRANTED.

PAUL NICHOLAS LEACH, Secretary

HETEROPHILE ANTIBODY IN THE TREATMENT OF PNEUMONIA

NORMAN PLUMMER, M.D.
NEW YORK

Forsman¹ in 1911 found that guinea pig tissues, when injected into the rabbit, produce a hemolytic immune serum not only for guinea-pig red blood cells but also for sheep red blood cells. The lack of biologic relationship between the

From the New York Hospital and the Department of Medicine, Cornell University Medical College.

¹ Forsman, J. and Widen. Die Herstellung hochwertiger spezifischer Sera ohne Verwendung von Schafblut. Ein Beitrag zur Lehre von heterologer Antikörperbildung. Biochem. Ztschr. 37: 97, 1911.

species producing the antigen and the species for which the antibody has an affinity suggested the term heterophile, in contradistinction to the term homologous for the usual type. One group of animals, the so-called guinea-pig type, contains heterophile antigen, and this antigen when injected into the body of another group of animals (so-called rabbit type) produces heterophile antibody. The human being does not have the heterophile antigen but does produce the antibody, the horse possesses the antigen and therefore cannot produce the antibody. The rabbit, again like the human being, produces heterophile antibody. Recently, Bailey and Shorb² showed that many different bacteria contain heterophile antigen. They have reported that all types of the pneumococcus in both rough and smooth forms contain heterophile antigen. This antigen, they find, is not type specific. It has been shown that an animal of the rabbit type, when immunized with pneumococci, develops a high titer of heterophile antibody, while an animal of the guinea-pig type, such as the horse, already shows the heterophile antigen and does not produce the antibody.

The proponents of heterophile serum reason "that ordinary antipneumococcus horse serum, because of its absence of heterophile antibody, is an incomplete immune serum." Furthermore they state that the antipneumococcus horse serum, because of its content of natural heterophile antigen in addition to the heterophile antigen of the pneumococci added in the process of immunization, when injected into the human being sick with pneumonia exerts a certain "antagonistic action" by neutralizing any natural heterophile antibody present in the human being.

The existence of heterophile bodies, the presence of heterophile antigen in the horse and heterophile antibody in the rabbit, in other words the Forssman phenomenon as a biologic condition, is accepted by most observers. This subject of heterophile phenomena in immunology has been reviewed and commented on by Leon Buchbinder.³ Buchbinder stresses the importance of this condition, he comments favorably on the use of heterophile antibody in passive immunization, and he predicts that the heterophile factor will have increasing importance in the production of immune serum.

The presence of heterophile antigen in the pneumococcus and other bacteria is based on the work of Bailey and Shorb⁴ at Johns Hopkins University. Since 1931 they have made several reports. They found that they could produce antiship hemolysis in the serum of rabbits, giving the characteristic reactions of heterophile antibody, by (1) injecting pneumococci subcutaneously and intravenously into the rabbits, (2) infecting rabbits with pneumococci, and (3) feeding killed cultures of pneumococci to rabbits. Further, they were able to remove the antipneumococcus hemolytic antibody from the serum by absorption either with homologous or heterologous boiled pneumococci or with boiled sheep corpuscles. The experiments of Bailey and Shorb were carried out further to show that 1 Rabbits immunized with heterophile antigens from animal sources particularly sheep corpuscles were relatively resistant to intravenous infection with type I pneumococci. 2 The protective property of antipneumococcus horse serum for mice was enhanced under certain conditions by the use of antiship hemolytic rabbit serum with it. 3 The opsonic power of whole and concentrated antipneumococcus horse serum for pneumococci can be greatly increased by combination with antiship or antipneumococcus rabbit serum.

The observations of Bailey and Shorb are excellently reported. However observations of such significance should be confirmed by an independent group of investigators before receiving final acceptance. The presence of heterophile antigen in the pneumo-

coccus and other bacteria and the production of heterophile antibody in the rabbit seem reasonable. Knowing the variability of results following the intravenous injection of pneumococci into the rabbit, and knowing the shortcomings of the mouse protection test, it is difficult to follow completely the conclusions that the resistance of rabbits can be increased and the protective power for mice enhanced by the use of heterophile bodies. As far as the increase in opsonic power is concerned, Goodner,⁵ who has been working along this line, feels that the cause of this increase is not yet known and that it may be a factor other than the heterophile antibody.

In order to show further evidence that heterophile antibody has biologic and therapeutic significance in pneumococcal infections, Powell, Jamieson, Bailey and Hyde⁶ at the Lilly Research Laboratories and at Johns Hopkins University repeated the Goodner experiment, producing type I, II and III pneumococcus dermal infections in rabbits and curing them with (1) antipneumococcus immune horse serum, (2) rabbit heterophile (anti-boiled sheep cell) serum, (3) rabbit antipneumococcus serum, and (4) mixtures of horse and rabbit antipneumococcus serum. They conclude that the usual pneumococcus mouse protective antibody is more effective therapeutically in rabbits when fortified with heterophile antibody.

This work of the Lilly investigators is excellently reported and if it can be repeated will throw new light on the entire subject of pneumococcus immunity. Since Goodner⁷ reported the pneumococcus dermal test in rabbits in 1928, it has been used quite extensively by various pneumonia investigators. Goodner, however, found the test applicable only to type I pneumococcus infections and his reports deal only with infections of this type. It has been found that only an occasional strain of type II or type III pneumococcus will produce the dermal infection. In my own experience certain virulent human strains of type II pneumococcus were pathogenic for rabbits only in extremely high dosage. This experience makes it difficult to follow the very consistent results procured by these experimenters. Their protocols do not indicate the difficulties reported by other investigators. Assuming that this work can be repeated, it still remains true that in this experiment the better results are reported when the infected rabbit is treated with rabbit serum and it still is a question whether it is better to go from the rabbit to the human being or from the horse to the human being.

The strongest argument in favor of heterophile serum given by its proponents is that convalescents from pneumococcal pneumonia show an increased titer of heterophile antibody in their serum. Bailey and Shorb⁴ report as follows: "A number of human sera were obtained from cases of lobar pneumonia near the beginning of the disease and soon after the temperature had returned to normal. These sera were titrated for antiship hemolysis. There was a definite increase in the hemolysis in the cases which recovered. For example, in one case infected with an organism reported as a type IV pneumococcus the titer of the serum on the fifth day of the disease was 16 units per cc, and at the end of the twelfth day (sixth afebrile) the serum contained 100 units of antiship hemolysis per cc. This represents the evidence in the literature showing that heterophile antibody is increased in the serum of convalescent pneumonia patients. On the other hand recently, Finland, Rueggesser and Felton⁸ have reported their finding of heterophile antibody (sheep cell hemolysis) in the serum of (1) convalescent pneumococcal pneumonia patients, (2) subjects immunized with potent pneumococcus antigenic fractions, and

(3) normal controls In all they tested 671 serums and included 120 pneumonia patients The titer of heterophile antibody was surprisingly the same in the three groups of cases, failing to show any increase in titer in the convalescent pneumonias and no decrease in the bacteremic or fatal cases In the pneumonia patients treated with antipneumococcus horse serum there was a decrease in hemolysin shortly after the injection of the serum and a definite rise a week or more later These changes in no way were found to correspond to the course of the disease. Finland, Ruegsegger and Felton felt that there was no justification for the contention that antipneumococcus horse serum in acting as a heterophile antigen is primarily toxic and has an antagonistic action They conclude that heterophile antibody has no bearing on the course or outcome of human cases of pneumococcic pneumonia

The manufacturers of the combined heterophile antibody serum admit that the clinical and statistical evidence is limited, however, they give the following "In a series of fifty cases treated, the mortality was 8 per cent, while in the control group it was 26 per cent The average number of days of hospitalization was twelve for the treated and sixteen and one half for the untreated Jameson and Powell reported on the use of the serum in five cases of pneumonia In four cases there was temporary marked drop in temperature and relief of toxemia One patient failed to respond When the triple combined serum was used in a small series of cases within seventy-two hours of onset of the disease, the mortality was 28.5 per cent as against 58.5 per cent when no serum was used No attempts were made to type the pneumococci."

Such a statistical report is not only limited in its scope but is extremely misleading Chance plays its part in the run of pneumonia cases in the same way that it plays its part in the run of cards I have seen as many as thirty consecutive deaths from pneumonia in the wards of Bellevue and a greater number of consecutive recoveries The practitioner who sees a number of pneumonia patients in his practice may go for several seasons without a single fatality and then may have several deaths in a row This shows the necessity of a large series and shows the importance of alternate controls In attempting to ascertain statistical evidence in pneumonia it has been found necessary to control a group of cases by having the following information (1) accurate type diagnosis, (2) blood culture determinations, (3) presence or absence of complications, (4) age of patient The mortality rate varies with each of these factors, and in addition it varies with each particular year and with the season of the year

The combined heterophile antipneumococcus serum has been marketed since September 1934 It is a mixture of the refined and concentrated serums of the horse and of the rabbit The horse immunization is carried out by the intravenous injections of virulent culture of types I, II, III and IV, and subcutaneous injections of whole culture toxic vaccines of the same types The rabbit immunization is produced by intravenous administration of virulent pneumococci high in heterophile antigen, and of the same four types The heterophile antigen in the horse serum is eliminated by adding the rabbit serum and removing the resulting precipitate An additional amount of rabbit serum is then used so that the final product will contain a certain amount of heterophile antibody in addition to the usual Felton units of protective substance The average horse fraction is estimated at from 80 to 90 per cent, and the rabbit fraction at from 10 to 20 per cent

The producers of this combined heterophile serum do not state why the Cooper type IV pneumococcus is used instead of one of the more important subtypes of group IV This will undoubtedly lead the average physician who is not familiar with the more recent classification of the pneumococci to believe that the immunization is complete for the usual types I, II and III and group IV pneumococcus, and therefore, that the serum gives passive immunization for all pneumococcic pneumonias Furthermore, it should be pointed out that several producers of antipneumococcus serum have found that

it is more difficult to immunize horses for several types than for one or two types I have noted that the Lederle bivalent type I and II serum requires almost double the amount of fluid that the monovalent type I serum of the same brand requires Were it not for this uneven immunization when several different types are used, it would be highly desirable to prepare type I, II, VII and VIII serum The producers of serum also have found it difficult to obtain horse serum in which type III and type IV antibodies have formed in any appreciable titer The manufacturers of the combined heterophile serum do not mention any of these difficulties, neither do they indicate the titer of type III or type IV protective substance in the serum

The fact that the heterophile serum contains the foreign proteins of both the horse and the rabbit theoretically doubles the chances for allergic reactions I have known of several instances of atopic rabbit sensitivity Acquired rabbit sensitivity is quite common among laboratory workers and probably occurs with some frequency in industries in which rabbit pelts are handled There are no statistics, but one is led to believe that rabbit sensitivity is almost as common as horse sensitivity

In their booklet the manufacturers state that patients receiving serum should be given a skin test using 0.1 cc of a 1:10 dilution of the serum, and an ophthalmic test with the same diluted serum Presumably, the serum referred to is the diluted therapeutic serum, which contains an indefinite amount of the horse and rabbit serum protein This certainly would give unreliable readings It would seem advisable, when the combined serum is used, to recommend two tests, one with the diluted whole horse serum and the other with the diluted whole rabbit serum In this way antipneumococcus horse serum, which has so much evidence for its value, could then be given to the type I patient sensitive to rabbit serum but not sensitive to horse serum

CONCLUSIONS

1 The presence of heterophile bodies in animal tissues, animal serums and bacteria is strongly suggestive that these bodies play a part in certain immune reactions

2 The animal experiments carried out by Bailey, Shorb, Powell, Jameson and Hyde do not prove that the heterophile bodies play a role in the pneumococcus immunity of the human being Some of the results reported are open to question The work should be repeated by an independent group of investigators before it is accepted

3 The study by Finland, Ruegsegger and Felton on the heterophile antibodies in the serum of patients convalescing from pneumonia and in controls leads one to believe that the heterophile bodies do not have any particular bearing on the course of pneumococcic infections in man

4 The clinical and statistical evidence cited by the manufacturers of the combined heterophile antibody serum is too limited and is strongly misleading

5 The presence of both rabbit and horse proteins in the serum will increase the incidence and the dangers of allergic reactions This is a definite disadvantage, because with newer methods of refining serum the allergic reaction is the principal source of danger in any type of serotherapy

6 There is only slight experimental evidence and no clinical evidence that the combined heterophile serum gives any immunity against type III and group IV pneumococcic infections There is the same lack of evidence that the combined serum produces a greater immunity for type I and type II infections than the ordinary antipneumococcus horse serum

7 The principal theoretical advantage of the combined heterophile serum is that it could be used for all pneumococcic pneumonias, regardless of type, and the corollary of this that pneumococcus typing would not be necessary Serum having this advantage would be highly desirable but because its superiority is unproved and because of the probable increase in allergic reactions it is unfair and unwise to recommend the combined heterophile serum for general distribution

RHEUMATIC INFECTION IN CHILDHOOD

The abdominal syndrome is one of the most frequently overlooked symptoms of childhood rheumatic disease. Wolfe and Brim,¹ writing in the current issue of the *American Journal of Diseases of Children*, call attention especially to a group of children in whom recurrent abdominal cramps lasting from six months to several years were apparently the only subjective manifestation of an active phase of rheumatic infection. The cramps lasted as a rule from a few minutes to a few hours and tended to recur frequently. At times the child complains of nausea and sometimes vomiting. The episode is usually closed before the next meal. Pain is felt frequently around the umbilicus for a short time but sometimes becomes generalized. Tenderness and rigidity are usually absent. Characteristic histories are difficult to obtain, and it is often not until evidence of organic cardiac disease is accidentally discovered that such experiences are related to a physician and then only after persistent and pointed questioning. Early recognition of this abdominal syndrome as a manifestation of rheumatic infection before the onset of organic heart disease becomes manifest may thus become in some instances of considerable importance. Except for dietary indiscretion, active childhood rheumatism is probably the most important cause for such abdominal symptoms, provided the attacks of cramps are transitory and apparently inconsequential. Other manifestations of the active phase may be associated with it, such as pallor, weight fixation in spite of a properly balanced diet, irritability without apparent cause, twitchings and tics, and enuresis after the control of the bladder has been established. The gastro-intestinal manifestations of rheumatic disease may be acute or chronic. The acute symptoms last for a short period, usually from one hour to three days. The attack commonly begins in the upper part of the abdomen, with a sharp nonradiating pain. It often occurs at night or in the morning after a hasty breakfast. The temperature is slightly elevated but rarely higher than

101 F. The pulse rate is not markedly increased. Diarrhea is the exception. The chronic form is characterized by mildness. After the subsidence of the acute attack, minor episodes of fleeting abdominal pain may recur from time to time without any other signs. Diarrhea alternating with periods of constipation is, however, a frequent phenomenon of the chronic form.

In the same issue of the *American Journal of Diseases of Children* Ash² discusses the prognosis in childhood rheumatic infections. Her information was based on 416 patients who had been under observation for two or more years. The average period of observation for the series was seven and one-half years. Of the total group traced, ninety-three, or 22.3 per cent, died as a result of rheumatic infection. Four children died of other causes. Valvular heart disease was present in 66.1 per cent. In 257 patients (57.7 per cent) the disease began with fever of varying degree associated with migratory articular pains of variable intensity. The average age at which these children came under observation was 7.6 years. The age at the last time of observation varied from 5 to 23 years, the average for the entire group being 14 years. From two to nineteen years had elapsed since the onset, the average duration being seven and one-half years. The differences in the death rate between this and other groups studied may be explained largely on the original criteria for selection perhaps more than by the intrinsic variation in the severity of the disease in different localities. In Ash's group there was a startling death rate in the children among whom the course of the disease was actually ten years or more. Of eighty-seven children traced after an average period of twelve years, 44.8 per cent were dead. Of 121 children with rheumatic infection, 40.5 per cent were dead ten years after the onset. Among the group of children whose infection had originated during the five years from 1922 to 1926, however, there were approximately twice as many deaths as among the group whose disease had started within the five years from 1927 to 1931. The meaning of this difference is not quite clear. It was evident, however, from her studies of the clinical nature of the infection and complications that the course of the disease is modified by such variables as sex, racial origin, age at the onset of the infection and calendar year of the origin. Among the clinical manifestations, pericarditis, rheumatic pneumonia, involvement of both aortic and mitral valves, the early appearance of a buttonhole stenosis and subcutaneous nodules bear the most ominous prognosis. Uncomplicated chorea is a mild manifestation. Epistaxis, abdominal pain, hematuria and multiform cutaneous eruptions may be placed in an intermediate group from the standpoint of their prognostic significance. There is some evidence that within recent years there has been a lowering in the mortality and in the incidence of cardiac involvement, though to what

factors this is due and whether the apparent improvement will persist remain uncertain

This highly fatal and crippling disease originating most frequently in childhood is worthy of the closest scrutiny. Since available methods of studying the disease in animals are essentially lacking, the careful observation of the individual manifestations of the disease and the lessons which statistical studies can supply furnish the most suitable angle for prophylactic and therapeutic attack. These two papers furnish creditable evidence of the value which such methods can supply

ANTIANEMIC SUBSTANCE IN NORMAL HUMAN URINE

Recent experimental work on the etiology of pernicious anemia has indicated that in normal persons, as contrasted with patients subject to pernicious anemia, an erythropoietic principle is formed by the interaction of gastric juice and some other material, perhaps of dietary origin, and that this substance is subsequently absorbed and stored in the liver. Apparently, in the normal person a sufficient concentration of the hematogenic principle is maintained in the blood stream to promote the normal maturation of the red blood cells in the bone marrow. It seems logical, therefore, to expect that a small amount of the "antianemic" substance might escape from the blood stream into the urine and that a careful examination of the latter fluid might reveal its presence.

A group of investigators¹ at the University of Louisville, in a study of this question have used the reticulocyte response of pigeons as an index of the erythropoietic potency of the test substances. Heated and unheated sterile morning specimens of human urine from six normal subjects were injected intramuscularly for five consecutive days into pigeons in amounts varying from 0.1 to 1.5 cc. per hundred grams of body weight. The proportion of reticulocytes in the blood of the test birds was determined daily for two weeks prior to injection, in order to determine the basal reticulocyte level, and then daily for six weeks after injection. Since nearly all pigeon erythrocytes contain at least one or more granules of a substance staining blue with the reticulocyte stain only those cells which showed a moderately heavy or heavy reticulation were counted as reticulocytes. The results obtained indicated that significant increases in the percentage of reticulocytes occurred in most instances following the injection of even the smaller doses of unheated urine, whereas the responses from injections of the heated samples were of less magnitude and indeed were frequently absent, particularly if the urine had been heated in free access to air. The peak of the reticulocyte rise occurred on an average of fifteen

days after the first injection, and the degree of the reticulosis obtained in many instances compared favorably with that obtained with a potent liver extract injected intramuscularly under comparable experimental conditions. These results, the authors believe, indicate the presence in normal human urine of some substance with a reticulocyte-stimulating activity. Furthermore, the data suggest that the concentration of the erythropoietic substance in urine is roughly one-tenth that in the liver extract employed. In further studies of a preliminary nature, some evidence was obtained which indicated a close similarity between the urinary hematogenic substance and the antianemic principle of liver. Both are partially at least thermostable, particularly in the presence of air, both are nonvolatile, and the solubilities of the two substances in different solvents appear to be similar.

Within the past few months, reports have appeared describing an erythropoietic activity of normal urine when administered to rats² or to guinea-pigs.³ Likewise another investigator⁴ has found that normal human urine administered rectally to patients with pernicious anemia produced a reticulocyte response. Suggestive as the results of the foregoing investigations may be, adequate confirmation of the work is still to be desired. According to some investigators the pigeon is an extremely variable, if not wholly unreliable, test animal for antianemic preparations, and similar criticisms have been made of the rat and the guinea-pig. Even patients with pernicious anemia are known to give reticulocyte responses to inert substances at some times. Nevertheless, reports of further work on the alleged erythropoietic principle of normal human urine, particularly studies of the effect of purified extracts in sufficient numbers of proved cases of pernicious anemia, will be awaited with interest.

OSMOTIC EFFECT OF CALCIUM IONS IN THE BLOOD

The biochemical relationships of calcium have received much attention and have become reasonably well defined. The recognition of the indispensability of this element in nutrition, the discovery of the calcium-mobilizing power of the hormone of the parathyroid glands and the demonstration of the influence of vitamin D on the utilization of calcium have added impetus to the already vigorous trend of investigation of the state in which this element exists in blood and other body fluids and the manifold functions it fulfils in the organism. The total calcium concentration in the serum remains rather constant—close to 10 mg. per hundred cubic centimeters. Physiologic studies involving the

variation of this value have demonstrated that the level of blood calcium constitutes one of the equilibria on which life depends. Perhaps the clearest description of the probable physical state of this element in the serum has been given by McLean and Hastings¹. From data on the blood of several species of experimental animals and of man they have concluded that the concentration of calcium ions depends on the serum protein concentration, and a mass action formula has been devised involving serum protein, calcium proteinate and calcium ions which fits the experimental observations. According to them, about half the total calcium of the serum is ionized and corresponds to that previously known as the "diffusible" or "ultrafiltrable" fraction, as it was known to pass through artificial membranes, whereas the remainder is almost all in combination with protein in a physical form not passing through the membranes.

Using the laboratory models as a guide, the physiologist has employed the *in vitro* observations as a basis for explaining the situation in the living organism as regards the physical state of the serum calcium and the consequent behavior as an electrolyte. Thus, approximately half of the calcium is assumed to pass freely across the capillary wall and to behave from the physicochemical point of view much as do the other inorganic ions. This view has received support from the comparison of the concentration of calcium in the plasma with that in cerebrospinal fluid, protein-poor edema fluid, serous exudates and transudates and synovial fluid, under ordinary conditions, all these body fluids contain roughly an amount of calcium corresponding to the "diffusible" portion of the calcium of the plasma. However, recent studies of Keys and Adelson² have thrown doubt on the ready diffusibility of the ionized calcium of the blood. Healthy young men were subjected to brief bouts of severe exercise. It has previously been shown that under these conditions the oxygen capacity and the plasma protein concentration increase, whereas there is a marked loss of water from the blood. The recent experiments show that there also takes place a rise in concentration of blood calcium following vigorous exercise. Calculations showed that, were this increase due only to the non-diffusible colloidal calcium (a reasonable assumption according to the existing views), an impossible hemoconcentration must have occurred. The Harvard investigators are thus forced to the conclusion that the capillary membranes are by no means freely permeable to Ca^{++} though very slow equilibrium may take place.

The retention within the blood vessels of most or all of the ionized calcium during the period when water has been lost from the circulation would exert a significant effect on the osmotic pressure of the blood. Making certain reasonable assumptions Keys and

Adelson estimate that in their experiments when the blood was concentrated following severe exercise the effective osmotic pressure due to the ionized calcium was from 10 to 20 per cent of the total colloidal osmotic pressure. In the normal steady state the osmotic effect of Ca^{++} in the blood is balanced by that in the extra capillary tissue fluid, the greater the hemoconcentration, the more effective does the Ca^{++} of the plasma become in restoring the blood volume to normal. These newer observations add further to the significance of calcium in the organism, to its other virtues must be added that of promoting homeostasis through resistance of changes in blood volume, a property dependent on the difficult diffusibility of this element.

Current Comment

BLOOD VISCOSITY IN HEART FAILURE

In comparison with distilled water, the average normal viscosity of human blood has been found to be about 5.32, any viscosity above 6 or below 4 has been considered to be abnormal. Some blood viscosity values have been reported by Markson¹ in a clinical study of congestive heart failure. Among twenty six cases, twenty-two showed viscosity values that varied from 12.4 to 6.5, three viscosity readings between 4 and 5, and one a viscosity reading below 4. The high viscosity values found were generally associated with an increase in the red cell count and in the size of the individual cell, two cases of syphilitic aortic regurgitation, mitral regurgitation and congestive heart failure were exceptions to the increase in cell size and cell count. The case in which the viscosity was under 4 was one of infective endocarditis and the blood culture was positive for the streptococcus. When gross edema was present, the blood viscosity appeared lowered in association with a diminished red cell count, these values rose rapidly however when diuresis was established, and the edema subsided. Thus when the condition improved under treatment there was a definite fall in the blood viscosity to normal limits in most of the cases and also a reduction in the red cell count and in the diameter and volume of the red cells. The administration of oxygen to the point of relief of dyspnea and cyanosis caused a slight but consistent reduction in the blood viscosity and also in the size and number of the red cells. The same changes occurred when venesection was performed. It would therefore seem that the increase in blood viscosity in congestive heart failure is related to the size of the red blood cells as well as to their number. An increase in the viscosity of the plasma is probably an additional factor. Sahli² quotes Hamburger as having shown experimentally many years ago that carbon dioxide in the blood raises the viscosity by increasing the size of the cells. Now the clinical study by Markson also seems to indicate a relation between enlargement of the red

cells and the increase in carbon dioxide in the blood in patients with congestive heart failure. The administration of oxygen to these patients reduced the blood viscosity less definitely than did general therapeutic measures and rest in bed. In the exceptions noted in the cases of infective endocarditis, the low viscosity was probably related to severe secondary anemia and to the bacterial toxins in the blood. This investigation confirms Allbutt's³ statement that in heart disease the excess of carbon dioxide raises the blood viscosity while access to oxygen lowers it and causes a reduction in the number of red cells. It also confirms the observation of others⁴ that in heart failure without edema blood viscosity tends to be increased, while in heart failure with edema blood viscosity is often decreased.

Medical Economics

VITAL STATISTICS IN SICKNESS INSURANCE

Vital statistics, however imperfect, are one of the chief means now available for measuring health longevity, and the progress of medical service in the battle against disease. Medical service is, to be sure, not the only element affecting morbidity and mortality statistics. Economic and social environment both past and present may have effects which cannot be accurately isolated by any present-day statistical technique. When all these modifying elements are taken into consideration, however, we are still faced with the fact that the rate of decline in disease, the length of life, and morbidity and mortality in general have declined in a ratio that more closely follows the progress of medical service than any of the other elements.

The health organization of the League of Nations compiles vital statistics for most of the world.¹ The most improved statistical technique is used to make these figures comparable. If it is possible to provide better medical service to the mass of the people by means of compulsory sickness insurance than through the private independent practice of medicine, that fact should in some way be reflected in these statistics.

The latest compilation of the Health Section of the League of Nations of the general death rate for all the reporting countries covers the period from 1911 to 1934. The statistics are standardized so as to allow for differences in ages in the different countries, but not of course for general social conditions. The countries that in 1934 had a death rate of less than 10 per thousand are the Union of South Africa, Australia, Canada, New Zealand, Norway and the Netherlands. Only Norway among these has a system of compulsory health insurance that has lasted for a considerable time, that of the Netherlands was introduced about five years ago.

The United States death rate is calculated at 11 per thousand. This includes the Southern states with a colored population not found in any European country. If this section were excluded and only the states having a population and a geographic location comparable to that of the European nations with compulsory insurance systems were considered this country would show a lower death rate than that of any of the insured countries.

Only one South American country, Chile, has a system of compulsory sickness insurance. This country had a death rate of 26.8 in 1934 as compared with 11.8 in Argentina and of 10 in Uruguay, in neither of which countries is there an insurance system.

A better test of the efficiency of medical service is found by a study of the death rates from certain diseases that are

peculiarly susceptible to medical treatment. Diphtheria is one of the best of such tests. A comparison of the insurance and noninsurance countries with regard to diphtheria morbidity and mortality has previously been made.²

According to the Annual Epidemiological Report of the League of Nations, previously quoted, there was no city in the United States or Canada that had a diphtheria mortality rate of more than 6 per hundred thousand in 1934, with the exception of New Orleans, with 6.2 and of Quebec with 12.4. On the other hand, the total mortality rate for diphtheria in fifty-two German cities was 11 per hundred thousand. In 121 English cities this rate was 11.6 per hundred thousand, and in fifty Spanish cities without health insurance, the rate was 5.2. In Australia (without health insurance) the rate varied from 14 in Auckland to 8.5 in Perth, while Christchurch in New Zealand (without compulsory health insurance) had no deaths from diphtheria.

Tuberculosis is another disease in which the morbidity and mortality rates are affected by the character of medical service. A detailed comparison of the tuberculosis sickness mortality rates in insurance and noninsurance countries was published in *THE JOURNAL* of April 20, 1935.³ The recent report of the League of Nations confirms the conclusions there made that the rate of decline in deaths from tuberculosis is more rapid in noninsurance than in insurance countries. The effect of the colored population makes the comparison of tuberculosis mortality rates highly disadvantageous to the United States, but, if the white population alone is considered, the death rate from tuberculosis is lower in nearly every section of the United States than in the European countries having elaborate systems of sickness insurance.

Infant mortality is also considered a general test of the quality of medical service. In 1934 the deaths of children under 1 year, per thousand live births, in the Union of South Africa was 61, Canada, 72, United States, 60, Australia, 44 and New Zealand, 32. These are all countries which do not have sickness insurance. The rate in some of the leading countries having highly developed systems of sickness insurance was as follows: Germany, 66, England and Wales, 59, Denmark, 64, Scotland, 78. Only three European countries had rates much below these. These were the Netherlands, 43, Sweden, 47, and Switzerland, 46.

Perhaps a fairer comparison is found when the statistics of infant mortality in the larger cities are compared. In the United States the mortality per thousand births of infants under 1 year of age was, in 1934, as follows:

| | | | |
|-----------|----|--------------|----|
| Boston | 57 | Los Angeles | 53 |
| Chicago | 48 | New York | 52 |
| Cleveland | 44 | Philadelphia | 54 |
| Detroit | 50 | Toronto | 48 |

In Australia and New Zealand the mortality in the same year was as follows:

| | | | |
|--------------|----|------------|----|
| Adelaide | 40 | Melbourne | 48 |
| Auckland | 38 | Perth | 41 |
| Brisbane | 43 | Sydney | 44 |
| Christchurch | 39 | Wellington | 41 |

In none of these cities is there any system of compulsory sickness insurance. In the insured nations of Europe, fifty-two German cities had an infant mortality of 60 in 121 English cities, 63 in Berlin, 59 in Glasgow, 98, and in London, 67. In South America in Santiago, Chile, with a system of compulsory insurance there were 244 deaths per thousand of infants under 1 year. Buenos Aires in Argentina, with no insurance, had 63.

The fact that by all these tests the countries without sickness insurance consistently make a better showing than those in which a large percentage of the population are cared for under insurance systems would seem to justify the conclusion that the people generally receive a better medical service where private practice is maintained than where the physicians are required to practice under insurance regulations.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

The Poliomyelitis Situation—The state health officer of Alabama reports that 247 cases of poliomyelitis were reported in the state from June 1 up to August 7. The heaviest concentration has been in Lauderdale, Limestone, Colbert, Morgan, Cullman and Jefferson counties. Birmingham is in Jefferson County, where forty-seven cases have occurred. Up to June 1 eleven cases had been reported.

Society News—At a meeting of the Alabama State Association of Railroad Surgeons in Birmingham, July 10, speakers included Drs. Samuel Kirkpatrick, Selma, on "Management of Eye Injuries by the Local Surgeon," and R. W. Waldrop, Bessemer, hernia. Dr. H. Earle Conwell, Birmingham, president of the Jefferson County Medical Society, displayed lantern slides of "Compressed Fractures of the Spinal Vertebrae."

CALIFORNIA

Western School of Public Health—The University of California and Stanford University have organized a Western School of Public Health to assist health departments of western states in the training of public health personnel. Social security funds are used to finance the school and the education of certain public health workers. Health officers, public health nurses, sanitary inspectors, public health statistical technicians and public health laboratory technicians in the ten western states are eligible on recommendation of their health officers for attendance at these courses, which will be given during the summer months. The object is to train those who are already employed in health departments, provided they are considered worthy of receiving additional education. Applicants for the regular work, which may lead to a degree in public health, will be asked to meet definite matriculation requirements and must be within certain specified age limits.

COLORADO

Cragmor Reopens the Main Building—The main building of Cragmor Sanatorium, at Colorado Springs, which was closed during the recent reorganization of the institution, has been opened after a complete renovation. Under the reorganization (*THE JOURNAL*, March 14, p. 927) the sanatorium was incorporated as a 'nonprofit, nonsectarian organization created for benevolent, charitable and humanitarian purposes and for the treatment of tuberculosis and other ailments' as well as for research work. It was established in 1906 with accommodations for twenty-five patients, its present capacity is 130 beds.

CONNECTICUT

New Milk Regulation Adopted—The New Haven Board of Health recently adopted a regulation requiring that all milk or cream brought into or produced in the city, for sale within New Haven, must be pasteurized or come from accredited certified herds or both.

Coordinating Agencies in Cancer Survey—The Connecticut Health Bulletin announces the completed plan of organization for the statewide cancer survey now under way. The state department of health, functioning through its bureau of preventable diseases, has recently become a coordinating unit in this program through an act of the legislature. It will handle statistical analyses of cancer mortality tabulation and analysis of cancer clinic records and public education, cooperating with the state tumor committee of the Connecticut State Medical Society. This committee, appointed to carry on an educational program now has two active committees, publicity and scientific. The latter has been instrumental in organizing the Association of Connecticut Tumor Clinics of which there are about sixteen now operating at various general hospitals in the state. The first step in the survey was a statistical study made by Mr. Herbert F. Hirsche and the appointment of Dr. Matthew H. Griswold, Kensington, to a newly created position as public health physician in the state department of health to specialize in cancer work. (*THE JOURNAL*, July 4 p. 43)

FLORIDA

Personal—Dr. Ralph E. Stevens, health officer of St. Petersburg, has been named chief physician at the Florida State Hospital, Chattahoochee, succeeding Dr. James H. Pound, who resigned.—Dr. Thomas E. Morgan, Jacksonville, has been appointed in charge of the newly organized health unit in Pinellas County, with headquarters in Clearwater.—Dr. James Willard McMurray, Bartow, has been appointed district health officer of West Florida with headquarters at Marianna.

Society News—At a meeting of the Lake County Medical Society, June 1, Dr. John S. McEwan, Orlando, discussed "Traumatic Surgery."—The Florida Medical Association will hold a "stag" picnic at the Dudsread Country Club, Orlando, August 29.—Drs. Emil Novak and John A. Tompkins Jr., both of Baltimore, were guests of honor at a buffet supper given by the Orange County Medical Society at the Orlando Country Club, June 27.—At a meeting of the Shrine Club of the Pinellas County Medical Society in St. Petersburg, June 19, Dr. Annette M. Bieker, St. Petersburg, read a paper on "Ultraviolet Ray in the Treatment of Erysipelas."

Graduate Institutes—The Florida Medical Association, cooperating with its committee on maternal welfare, sponsored a series of graduate medical institutes on maternal and child health, June 1-16. Each institute lasted two days and consisted of afternoon and evening sessions, with Drs. Everett D. Plass, professor and head of the department of obstetrics and gynecology, State University of Iowa College of Medicine, Iowa City, and Samuel F. Ravenel, pediatrician, Greensboro, N. C., as the lecturers. The institutes were conducted in cooperation with the local medical societies and were held in West Palm Beach, Miami, Fort Myers, Tampa, Lakeland, Orlando and Daytona Beach.

IDAHO

New Health Units—Dr. Marion W. Caskey, Tynlorsville, Ky., has been appointed head of a new health unit at Lewiston, one of ten to be established in the state. Dr. Lester C. Krotcher, Coeur d'Alene, has been placed in charge of a unit at Twin Falls.

ILLINOIS

Memorial Archway to Leonard Wood—A stone archway was dedicated at Fort Sheridan, July 28 as a memorial to Major Gen. Leonard Wood, founder of the Citizens Military Training Camps. The archway, which stands at the entrance to the citizens military training camp area, was built by men of the army post under the auspices of the Chicago Historical Society and the Military Training Camps Association. General Wood graduated from Harvard Medical School, then practiced medicine in Boston, then was appointed an assistant surgeon in the army in 1886. He had a distinguished record in the Spanish-American War, after which he was appointed military governor of Cuba. He was commissioned brigadier general in the regular army in 1901 and major general in 1903. He served in the Philippines as governor of the Moro province from 1903 to 1906 and as commanding general of the Philippine Division until 1908. General Wood was partly responsible for the creation of the general staff of the army and served as its first chief from 1910 to 1914. He originated the so-called Plattsburg plan of training reserve officers and during the World War trained the eighty-ninth division of the National Army, and the tenth division of the regular army. In 1921 he was made chairman of a special commission to the Philippine Islands, and then governor general, a position he occupied at the time of his death in 1927.

Chicago

Society News—At a recent meeting of the Chicago Urological Society, the following officers were chosen: Drs. Harvey A. Berkey, president, William J. Baker, vice president, and Colquitt Otis Ritch, secretary.—Newly elected officers of the Chicago Society of Internal Medicine are Drs. Walter L. Palmer, president, Andrew C. Ivy, vice president, and Clarence F. G. Brown, secretary.

Graduate Course on Tumor Pathology—A graduate course in tumor pathology will be held September 21-27, with morning sessions at the Palmer House and afternoon sessions at Michael Reese Hospital. Wednesday, September 23, the program will be offered at the Veterans Administration Facility, Hines, Ill. The course is arranged in the form of clinics, lectures, demonstrations and round table conferences and speakers will include Sir George Lenthal Cheate, London, England; Dr. Henri Coutard, director of x-ray therapy, Curie Institute, Paris, France; Dr. Max Cutler, director of the tumor clinic,

Michael Reese Hospital, Arthur H. Compton, Ph.D., professor of physics, University of Chicago, and Gioacchino Failla, D.Sc., physicist at Memorial Hospital, New York. At the banquet in the Palmer House Saturday evening, Dr. Morris Fishbein, editor of *THE JOURNAL*, will deliver an address.

Fund for Visiting Professorship—A fund has been established at the University of Chicago in memory of the late Dr. George Neil Stewart, from 1905 to 1907 professor of physiology at the university, and subsequently until his death in 1930 professor of experimental medicine and director of the H. K. Cushing Laboratory of Experimental Medicine at Western Reserve University School of Medicine, Cleveland. The fund, to be known as the G. N. Stewart Memorial Fund, is to be devoted to the research of Dr. Julius M. Rogoff, who has been appointed visiting professor of physiology. Dr. Rogoff, who collaborated with Dr. Stewart at Western Reserve for fifteen years, was until 1934 associate professor of experimental medicine. Since that time he has continued his investigations at the University of Chicago on the physiology of the adrenal glands, with particular reference to their relations to diabetes and hypertension. The fund was established through the contributions of the Louis D. Beaumont Trust, N. L. Dauby, Richard H. Kohn, Frances W. Lang and Howard E. Wise, Cleveland.

IOWA

Society News—At a meeting of the Buchanan County Medical Society, June 11, Dr. Lawrence P. Engel, Kansas City, Mo., among others, discussed 'Empyema of the Chest'.—Dr. Frank H. Krusen, Rochester, Minn., addressed the Floyd County Medical Society in Charles City, June 23 on 'Relationship of Physical Therapy to General Practice'.—The Hardin County Medical Society was addressed in Iowa Falls, June 30, by Dr. Samuel F. Haines, Rochester, Minn., on 'Glands of Internal Secretion'.—Speakers before the Jackson County Medical Society in the Bellevue State Park, June 18, were Drs. Howard R. Hartman, Rochester, Minn., on 'Disease of the Biliary Tract and Jaundice', James C. Kessler, Iowa City, 'Common Skin Diseases', and Horace M. Korns, Iowa City, 'Recent Advances in Diagnosis and Treatment'.—Dr. Herbert W. Rathe, Waverly, discussed 'Coronary Artery Disease' before the Tama County Medical Society in Tama, June 5.—At a meeting of the Webster County Medical Society in Fort Dodge, June 19, Dr. William A. O'Brien, Minneapolis, read a paper entitled 'Medicine Marches On'.

MASSACHUSETTS

Personal—Dr. Leroy M. S. Miner, professor of clinical oral surgery and dean, Harvard Dental School, was installed as president of the American Dental Association, July 16. Dr. Miner took his dental degree at Harvard and his medical degree at Boston University School of Medicine.—Dr. K. H. Gieritz, Stockholm, recently gave three lectures at the Peter Bent Brigham Hospital on 'Twenty-Five Years of Experience in the Treatment of Peritonitis', 'Thrombo-Embolic Disease and Its Surgical Treatment' and 'Development of Respiratory Apparatus for Thoracic Surgery'.

MICHIGAN

Expansion of Health Activities—An allocation of \$280,293 for public health activities in Michigan under the Social Security Act has been made available to the state department of health for the current fiscal year. In addition, \$89,352.85 has been assigned to the bureau of child hygiene and public health nursing by the children's bureau; this money will be used to extend services to mothers and children in rural areas, in areas suffering from economic distress and among groups in special need. A new bureau of industrial hygiene has been created in the state department of health and Menominee County has voted to establish a full-time department of health by October, newspapers reported.

Personal—Dr. Mark S. Knapp, Ann Arbor, has resigned as executive secretary and director of medical research of the Horace H. and Mary A. Rackham Fund, Detroit. Dr. Knapp had held the position since the fund was created in 1934.—Dr. Walter E. Mercer, for four years health officer of Webberville, has been placed in charge of the bureau of child health of the Lansing department of health.—Dr. Frederick G. Novy, dean emeritus and professor emeritus of bacteriology, University of Michigan School of Medicine, Ann Arbor, received the honorary degree of doctor of laws at the ninety-second commencement of the University of Michigan. This was the fiftieth anniversary of Dr. Novy's graduation from the university.

MINNESOTA

Society News—Dr. Everett C. Hartley, St. Paul, addressed the Northwestern Pediatric Society in Rochester, July 11, on 'Maternal and Child Welfare Legislation'. Dr. Waltman Walters, Rochester, showed a motion picture on 'Surgical Management of Congenital Abnormalities of the Genito-Urinary Tract'.

Hospital News—About 200 children on the waiting lists of the Gillette State Hospital for Crippled Children, St. Paul, the Eustis Children's Hospital and the Shriners Hospital, Minneapolis, will be hospitalized with social security funds now available. Some of these children have been waiting as long as two or three years, it was reported. Dr. Herman E. Hilleboe, St. Paul, will direct the state's crippled children program.

NEBRASKA

Health at Omaha—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended August 1 indicated that the highest mortality rate (201) appeared for Omaha and that the rate for the group of cities was 99. The mortality rate for Omaha for the corresponding week of 1935 was 205 and for the group of cities, 10. The annual rate for the eighty-six cities was 128 for the thirty-one weeks of 1936, as against a rate of 119 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for a large area or that it has a large Negro population may tend to increase the death rate.

State Council on Medical Education—The Nebraska State Medical Association has formed a council on medical education to direct its educational activities. The council consists of a general chairman, the deans of the two medical schools in the state, the chairman of each educational activity, the president, the president-elect and the executive secretary of the state association. Dr. William P. Wherry, Omaha, is general chairman, and Dr. J. Stanley Welch, Lincoln, vice chairman. Other members are Drs. Charles W. M. Poynter, dean and professor of anatomy, University of Nebraska College of Medicine, Omaha; Bryan M. Riley, dean, Creighton University of Medicine, Omaha; Joseph D. McCarthy, Omaha speakers' bureau; Earl C. Sage, Omaha, maternal welfare; Ernest W. Hancock, Lincoln, tuberculosis; James F. Kelly, Omaha, cancer; Claude T. Uren, Omaha, hard of hearing; and James E. M. Thomson, Lincoln, fractures. George W. Covey, Lincoln, president; Roy W. Fouts, Omaha, president-elect; and Mr. M. C. Smith, Curtis, executive secretary. The council held its first meeting, June 23, and made plans for its work. A faculty from members of the association will be organized to prepare addresses to be used in graduate courses, talks for presentation to lay audiences and discussions to be used in county and district medical society meetings. The council will act as editorial critic and adviser to members in preparation of these addresses if desired. It was also agreed that whenever possible the results of special investigations become part of the educational program and that the activities of the council be united whenever possible with those of national and governmental units such as the state board of health, the American Society for the Control of Cancer and the National Tuberculosis Association.

NEW HAMPSHIRE

Food Poisoning Following Picnic—An outbreak of food poisoning occurred in Manchester, July 5, following a banquet during a convention of the organization known as 'Jehovah's Witnesses'. About 700 attended the meeting, which was held in a hall that had only a small refrigerator. The banquet began at 1 p.m. and about 4 o'clock during a speaking program the first victims began to be sick. An hour and a half later, when the health officer arrived, everything had been packed up, including the remains of any food, and a hasty exodus was in progress. About eighty-seven persons are known to have been treated in various towns in New Hampshire, having been stricken at intervals along their way, but the total number affected will never be accurately known, the health department bulletin pointed out. Symptoms were typical of food poisoning: nausea, dizziness, vomiting, diarrhea and intense abdominal pain. In spite of the fact that adequate tests could not be made, the health officials believed that the illnesses were caused by infection of one or more items of the food by some organism with subsequent rapid multiplication resulting from failure to hold the food at a lowered temperature.

NEW JERSEY

Society News—Dr Herbert T Kelly, Philadelphia, discussed diabetes at a meeting of the Cumberland County Medical Society, Millville, June 9.—Speakers before the Middlesex County Medical Society, Marlboro, June 17, were Drs Joseph Berkeley Gordon, on "Methods of Committing Mental Patients in New Jersey" Elsworth F Baker, "Functional Psychoses," and Diomedes Guertin, "Organic Psychoses"—Dr Harrison S Martland, Newark, addressed the Monmouth County Medical Society in June on "Medical Detection of Crime"

State Society Surveys Hospitals—The committee on medical practice of the Medical Society of New Jersey is making a survey of the general hospitals in the state. A sixteen page questionnaire has been distributed to about eighty hospitals. Questions are asked about administration, rates, business management, the medical staff and its relation to the administration, methods of appointment dispensary and out-patient staff, control of patients compensation and liability cases, laboratory service, hospitalization insurance and the pharmacy

NEW YORK

Memorial to Dr Jacobi—A grove of trees near the summer home of Dr Abraham Jacobi at Bolton Landing on Lake George was dedicated as the Abraham Jacobi-Carl Schurz Memorial Park, June 13, at the close of the annual meeting of the American Pediatric Society. A boulder with a bronze tablet was placed in honor of Dr Jacobi and the Carl Schurz Memorial Bench, formerly by the roadside a short distance from the grove, was moved and rededicated. Dr Jacobi, who died in 1919, was a pioneer pediatrician, he occupied the first chair in pediatrics in America and was President of the American Medical Association in 1912. The grove, which has been given to the village by Dr Jacobi's daughter, Mrs George McAneny, is part of a wood where Dr Jacobi and his friend Carl Schurz spent many hours in their declining years. Dr Frederic W Schlutz, Chicago, presided at the ceremony, and speakers were Dr Isaac A Abt, Chicago, Dr Frederic E Sondern, New York, Dixon Ryan Fox, Ph D, Schenectady, president of Union College and president of the New York State Historical Society, and Mr McAneny, son-in-law of Dr Jacobi

New York City

Society News—Speakers at the meeting of the Medical Society of the County of Queens, September 29, will be Drs Royd R. Sayers of the U S Public Health Service, Washington, D C., on "Silicosis, Evaluation in Relationship to Tuberculosis", James Burns Amberson Jr., "Epidemiologic and Social Phases of the Tuberculosis Problem," and Abraham Braunstein, "Practical Application of the Newer Methods of Treatment of Tuberculosis"

Study of Silicosis—The New York City Department of Health, Cornell University Medical College, New York Hospital and the New York Tuberculosis and Health Association are conducting a study of silicosis, made possible by an appropriation of \$91,944 from the Works Progress Administration. About 3,000 workers exposed to dust will be examined and some will be admitted to wards of New York Hospital, where intensive bacteriologic and pathologic as well as clinical studies will be carried out.

Personal—Dr John J Kindred who is also a lawyer received the honorary degree of doctor of laws at the recent commencement of John B Stetson University, DeLand, Fla. where he has for several years taught medical jurisprudence. Dr Kindred was the first president of the National Association of Private Psychiatric Hospitals organized in 1934. He was for ten years representative in Congress from the second New York congressional district.—The honorary degree of doctor of science was conferred on Dr Simon Flexner, member emeritus of the Rockefeller Institute for Medical Research by the National University of Ireland Dublin July 20.—Dr Alfred Appelbaum has been appointed assistant professor of ophthalmology and assistant attending ophthalmologist at the New York Medical College and Flower Hospital

Max R. Schneller Sentenced to Prison—Maximilian R. Schneller who has practiced medicine without a license in various states and served penitentiary sentences for various offenses has been sentenced again for larceny. Schneller's latest legal entanglement occurred while he was with the New York City Board of Education on an assignment from the Works

Progress Administration as a psychologist and psychiatrist. He took from the mail a check made out to a teacher, and endorsed it. On representation of his counsel that a plea of guilty to attempted forgery would necessitate his deportation to Germany where he would be executed as a result of conviction of treason during the World War, he was allowed to plead guilty to petit larceny instead. Schneller had been paroled in September 1935 from the New York County Penitentiary, to which he was sentenced in April 1934 after he was found to be practicing without legal authorization as physician to Hart's Island Prison (THE JOURNAL, May 12, 1934). The probation department and the psychiatric clinic of the New York Court of Special Sessions made an exhaustive investigation of Schneller's history. It was found that he was born Max Schneller in Munich, Germany, in 1896. In 1912 he was under observation in the psychiatric division of the University of Munich and in 1914 was in a hospital in Tournay, Belgium, with a diagnosis of hysteria, the court reported. Between 1912 and 1923, the year in which he came to the United States, he was several times convicted, once for burglary and once for assisting to treason, among other offenses. The psychiatric examination disclosed no evidence of defective intelligence but a psychopathic personality with extremes of emotional reactions. His attempts to represent himself as a physician indicate a definite pathologic trend, the report said, he has no medical education whatever.

NORTH DAKOTA

Appointments in State Health Department—Dr Harnet Bixby, Boston, has been appointed state bacteriologist and Dr August C Orr, Searles, director of the child hygiene division in the state department of health. Dr Bixby succeeds A W Ecklund Bismarck, who resigned. Dr Orr's appointment marks reestablishment of the division of child hygiene with social security funds after a lapse of several years.

OHIO

Gift for Research—The University of Cincinnati has received a gift that in five years will amount to \$55,000 from Mrs Louise Fleischman Yeiser to establish in the college of medicine the Craig Yeiser Memorial Fund in Preventive Medicine. She will give \$10,000 a year for five years and an additional \$5,000 for equipment to carry on research in preventive medicine in memory of her son, who died in 1935 of pneumonia.

Society News—The Eighth District Medical Society met at Rocky Glen Sanatorium, McConnelsville, June 25, with the following speakers: Drs John H J Upham, Columbus President-Elect of the American Medical Association on "These Changing Times" Sidney M McCurdy, Youngstown "Medical Problems in Industry", Emery R Hayhurst, Columbus, "Silicosis," and Walter R Griess, Cincinnati, "Treatment of Gastric Ulcer, with Special Reference to Emetine Hydrochloride"—Dr Arthur C Morgan, Philadelphia, addressed the Summit County Medical Society, Akron, June 2, on "Applied Therapeutics"

Personal—Dr William E. Thompson, Bethel, celebrated his one hundred and first birthday July 6.—Dr William Dean Collier professor of pathology, St. Louis University School of Medicine, has accepted a position as head of the department of pathology at St. Elizabeth's Hospital, Youngstown, to succeed Dr Robert B Poling who resigned to devote his time to private practice.—Dr Vaughn L Hartman, Medina has been appointed health commissioner of Medina County.—Dr Cyrus R Wood, Port Clinton has been appointed health officer of Ottawa County to succeed the late Dr Charles B Finelrock.—Dr John D Dunham, Columbus, has been appointed to the city board of health to succeed the late Dr Wells Teachnor Sr.—Dr Arthur H Franks Akron, recently took a degree in law at the Akron Law School.

PENNSYLVANIA

Hospital News—Bryn Mawr Hospital recently received \$42,000 from the annual Devon Horse Show and County Fair.—The state treasury recently mailed checks amounting to \$1,000,000 to state aided institutions, about half what is due them it is reported.—St. Mary's Mater Misericordia Hospital Scranton has recently opened a tumor clinic. Records accumulated during many years by the late Dr Jonathan M Wainwright Scranton have been made available to the clinic for study and research. Dr Wainwright was chairman of the cancer commission of the Medical Society of the State of Pennsylvania.

District Meetings—The annual meeting of the Eleventh Councilor District of the Medical Society of the State of Pennsylvania was held at Bedford Springs, July 16. Papers were presented by Drs Roy W Scott, Cleveland, on "Diagnosis and Management of Coronary Artery Disease", Randle C Rosenberger, Rahns, "Foods, Their Preservation and Food Poisoning," and John O Bower, Philadelphia, "Appendicitis Mortality in the Eleventh Councilor District". The following officers of the state society discussed organization problems. Drs Alexander H Colwell, Pittsburgh, president, Walter F Donaldson, Pittsburgh, secretary, and Chauncey L Palmer, Pittsburgh, chairman, committee on public health legislation. The Ninth Councilor District held a meeting at the Kittanning Country Club July 30, at which Dr Robert L Anderson, Pittsburgh, spoke on "Modern Methods of Treating the Enlarged Prostate Gland", Dr Maxwell Lick Erie, "Early Diagnostic Essentials in Abdominal Conditions", Dr Laurrie D Sargent Washington, "Hypotension" and Dr Milton M Auslander, Ernest, "Maternal Mortality in the Ninth Councilor District". Dr Colwell made an address on "The Incompatibility of the Economics of Business and the Ethics of Medicine". Dr Palmer, on "Federal Social Security Contribution to Pennsylvania Health Activities," and Dr Donaldson, "Our State Society".

RHODE ISLAND

Fiske Fund Prize Essay—The trustees of the Fiske Fund, administered by the Rhode Island Medical Society have announced that the subject for the 1937 essay will be "Newer Methods of Prevention and Treatment of Acute Anterior Poliomyelitis". The prize is \$250. Competitors should forward copies of their dissertations, marked with a motto to the secretary on or before May 1, 1937. They must be typewritten should not exceed 10,000 words and should be accompanied by a sealed envelop bearing the motto on the outside and the name and address of the sender within. The author of the successful dissertation must transfer to the trustees his right, title and interest in it for the use of the Fiske Fund. Letters accompanying the unsuccessful dissertations will be destroyed unopened and the papers may be obtained by their authors if requested within three months. The secretary is Dr Wilfred Pickles, 184 Waterman Street, Providence.

SOUTH CAROLINA

Society News—At a meeting of the Fifth District Medical Society in Winnsboro in May, speakers included Drs Richard M Pollitzer, Greenville, on infantile paralysis. Henry W deSaussure, Charleston, fatal accidents of pregnancy and Austin T Moore, Columbia, management of fractures. Speakers at the semiannual meeting of the First District Medical Association at Walterboro, May 28, included Drs F Adelbert Hoshall, Charleston on Fractures of the Leg and William H Prioleau, Charleston, "Removal of Needles from the Hand". Drs James R Howell and William A Whitlock Jr, Aiken, addressed the Ridge Medical Association, Batesburg, June 15, on Emergency Operations and Anesthesia and Treatment of Hemorrhoids respectively.

TENNESSEE

New Hospital Superintendents—Dr Henry Bryan Brackin, Nashville, has been appointed superintendent of the Davidson County Hospital, near Nashville to succeed the late Dr William W Core. Dr Raymond R Crowe of the staff of the Davidson County Tuberculosis Hospital Nashville has been appointed superintendent to succeed the late Dr Blackburn G Tucker. Dr Jewell R Wilson of the staff of the Western State Hospital has been named head of the institution to succeed Dr Edwin W Cocke, who resigned recently.

TEXAS

Society News—At a meeting of the Cooke County Medical Society in Gainesville June 8 Drs Milton L Martin and Priestley Lipscomb, Denton, spoke on medical history and prevention of sinus infection respectively. Drs James Vance and John L Murphy, El Paso, addressed the El Paso County Medical Society in May on Intra-Abdominal Ovarian Hemorrhage and Varicose Ulcers and Their Treatment respectively. At a meeting of the Kaufman County Medical Society June 2, speakers were Drs David W Carter Jr, Dallas on Treatment of Diabetes. Loman C Carter, Marlin "Coronary Heart Disease" and Gough H Alexander Terrell "Newer Aspects in the Treatment and Diagnosis of Peptic Ulcer". Drs George H Beavers Jr and William Porter

Brown, Fort Worth, among others addressed the Tarrant County Medical Society Fort Worth, recently on "Abruptio Placentae" and "Limitations of Radiation Therapy in Dermatology," respectively.

UTAH

Plague Infection—According to *Public Health Reports*, bacteriologic examination for plague was positive in a boy bitten by a ground squirrel, June 24 near Beaver. Beaver County Ground squirrels from a ranch two miles north of Bone, shot June 23, and from a ranch four miles southwest of Bone June 24 were proved to be plague infected. Fleas taken June 25 and 26 from seventy-five squirrels on the latter ranch were found positive for plague.

WEST VIRGINIA

Physician Appointed to Social Security Council—Dr William S Fulton, Wheeling has been appointed by Governor Kump to the new State Public Assistance Council which will carry out the state's social security program under a new state law. Dr Fulton's appointment is for six years.

Annual Clinic—The annual program presented by the Golden Clinic of the Davis Memorial Hospital, Elkins, was given July 16. Clinics were conducted in the morning at the hospital. In the afternoon addresses were made by Drs Moses Paulson, Baltimore, on "Common Diseases of the Digestive Tract", Albert E Goldstein, Baltimore, "Renal Disorders in General Practice" and Lloyd F Craver, New York, "The Lymphomatous Diseases". A motion picture showing a technique for correction of inguinal hernia, produced at the Golden Clinic was presented. At a banquet in the evening Dr Robert J Wilkinson, Huntington, was toastmaster and the speaker was Dr Frank E Adair, New York, on "Tumors of the Breast".

WISCONSIN

Graduate Courses—Three new circuits for the graduate courses in obstetrics and pediatrics conducted with the aid of federal funds have been announced. Drs Otto H Schwarz, St Louis, and Francis R Janney, Wauwatosa began one July 20 at Balsam Lake, continuing at Hudson, Menomonie, Eau Claire and Ladysmith. The second began July 27 with Drs Fred L Adair, Chicago, and Horace K Tenney Jr, Madison, as instructors at the following towns: Marinette, Shawano, Fond du Lac, Wausau and Antigo. The third also began July 27 with Drs John W Harris and John E Gonce Jr, Madison, as instructors at Park Falls, Hayward, Superior, Ashland and Rhinelander.

Foundation Patents Pituitary Hormones—The U S Patent Office has recently issued to the Wisconsin Alumni Research Foundation two patents on the isolation and purification of the gonadotropic hormones of the anterior pituitary gland. These patents (Nos 2030209 and 2030210) were on the application of Frederick L Hisaw, Ph D, and Harry L Fevold, Ph D, Madison and were assigned by them to the Wisconsin Alumni Research Foundation. The foundation announces that although it contributed in part to the development of this research through grants in aid, it will administer these patents in a way designed to benefit the public without thought of any financial return other than that required to safeguard and control proper use of the products. Under these conditions Dr Hisaw and Dr Fevold will not receive any pecuniary reward for their discoveries.

WYOMING

State Medical Meeting at Cody—The thirty third annual meeting of the Wyoming State Medical Society will be held at Cody August 24-25 under the presidency of Dr Joseph L Wicks. Evanston. Scientific papers will be delivered by the following:

Dr Wicks (presidential address) "Forty Years Progress in Medicine."
Dr Joseph C Buntin, Cheyenne "Nephropathy and Its Treatment."
Dr George R James, Casper "Squint—A Problem of the General Practitioner."
Dr George H Phelps, Cheyenne "Recent Trends in Obstetrics."
Dr Reuben J Boesel, Cheyenne "Injection Treatment of Hernia."
Dr Peter M Schunk, Sheridan "Use of the Ultraviolet Ray in the Treatment of Erysipela."
Dr Frederick L Beck, Cheyenne "Acute Otitis Media."
Dr William Andrew Buntin, Cheyenne "Localization of Brain Tumors."
Dr Harry H Wear, Denver "Prelitus with Special Reference to Treatment."
Dr Thomas D Cunningham, Denver "Diagnosis and Treatment of Peptic Ulcer."

Guest speakers will include Drs John H J Upham, Columbus Ohio, President-Elect, American Medical Association on "Heart Disease in Middle and Past Middle Life." Claude F

Dixon, Rochester, Minn., "Acute Abdominal Disease", John R. Nilsson, Omaha, "Surgical Conditions of the Esophagus," and William F. Braasch, Rochester, Minn., "Practice of Medicine Under State Control." There will be a smoker Sunday evening and a golf tournament at the Cody Golf Club, Monday morning. The woman's auxiliary also has a program planned for August 24-25.

GENERAL

Board Examination in Gynecology and Obstetrics—The American Board of Gynecology and Obstetrics announces that its next written examination and review of case histories will be held in various cities in the United States and Canada, Saturday November 7. Application blanks and booklets of information may be obtained from Dr. Paul Titus, secretary of the board, 1015 Highland Building, Pittsburgh. Applications should be filed in the secretary's office sixty days before the date of examination.

Automobile Deaths Decrease in Six Months of 1936—There were 500 fewer automobile deaths during the first six months of 1936 than in the similar period in 1935, according to a report in the *Chicago Tribune* based on figures from the National Safety Council. This decrease was noted despite an 8 per cent increase in highway travel in the nation, it was stated. There were 15,390 traffic fatalities up to July 1 this year as compared with 15,890 for the same period last year. Deaths for June of this year, however, were about 5 per cent above those for the same month in 1935. Twelve eastern states having standard drivers' license laws and other effective motor vehicle control measures showed a reduction in automobile fatalities of 10 per cent, contrasted with the national decrease of only 3 per cent, it was stated. Chicago was the only city of more than 500,000 population to show an increase in these deaths during the six months period, the total was 367, one more than for the same period last year.

German Surgical Instruments Not Now Subject to Increase of Duty—Surgical instruments imported from Germany pursuant to contracts consummated subsequent to July 25, 1936 will not be subject to the increase in duty of 56 per cent of the invoice value that was imposed by a Treasury decision effective July 11 last. This countervailing or increased duty was imposed to offset certain bounties paid by the German government to German exporters of surgical instruments to the United States that enabled such exporters to compete in the domestic markets to the disadvantage of our own manufacturers (*THE JOURNAL*, 106 2163 [June 20] 1936). Since the imposition of the countervailing duty, however, the Treasury Department has received official advice that for any transactions concluded after July 25 the German government will neither pay nor permit the payment of any bounty to exporters of surgical instruments to the United States. The countervailing duty remains effective, apparently, with respect to surgical instruments that arrived in this country from Germany between July 11 and July 25 and to shipments contracted for prior to July 25 but arriving after that date.

Annual Congress of Physical Therapy—The fifteenth annual scientific and clinical session of the American Congress of Physical Therapy will be held at the Waldorf Astoria, New York, September 7-11. An educational conference will be conducted Monday afternoon with the following speakers:

Dr. Oswald N. Andersen, Council on Medical Education and Hospitals, American Medical Association, Chicago. Educational Standards for Physical Therapy Technicians.

Dr. Grant E. Ward, associate in surgery, University of Maryland School of Medicine, Baltimore. Teaching Value of the Cancer Clinic in Medical and Dental Schools.

H. H. Horner, assistant commissioner of higher education, state department of education, Albany. Ten Years Experience with Licensing Physical Therapists.

Margaret Oliver Hewlett, director, department of occupational therapy, Presbyterian Hospital, New York. Some Aspects of Occupational Therapy as Demonstrated in a General Hospital.

Marion G. Smith, registrar, Chicago American Registry of Physical Therapy Technicians.

At the opening session Tuesday evening Dr. William Bierman, New York, who will be installed as president, will speak on "Electricity and Medicine." The fourth annual William Benham Snow Memorial Lecture will be delivered by Major Oral B. Bolbaugh, medical corps, U. S. Army, on "The Role of Physical Therapy in Fractures." The session will conclude with an address by Dr. Norman B. Cole, assistant director of physical therapy, Johns Hopkins Hospital, Baltimore, entitled "Pathologic Changes of the Circulation." The general program will include symposiums on iontophoresis, fractures, vascular diseases, dermatology, fever therapy, arthritis, clinics and clinical conferences. The annual dinner will be held Wednesday evening.

Society News—Dr. Frank H. Lahey, Boston, was chosen president-elect of the American Society for the Study of Gout at its recent annual meeting in Chicago, and Dr. Nelson M. Percy, Chicago, was inaugurated as president.—Dr. Charles E. Sears, Portland, Ore., was chosen president-elect of the Pacific Northwest Medical Association at its annual session in Portland July 11, and Dr. Russell T. Congdon, Wenatchee, Wash., was installed as president. Vice presidents elected are Drs. Richard C. Monahan, Butte, Mont., and Samuel E. Lambert, Spokane, Wash. The 1937 meeting will be in Great Falls, Mont.—Dr. Marion T. Davidson, Birmingham, was chosen president of the Chattahoochee Valley Medical Association at its recent meeting in Albany, Ga. Other officers are Drs. Edgar H. Greene, Atlanta, and Clayton E. Royce, Jacksonville, vice presidents, and Frank K. Boland, Atlanta, secretary.—The American Association of Industrial Physicians and Surgeons will hold its annual meeting at the Hotel Traymore, Atlantic City, October 5-6. Dr. Volney S. Cheney, Chicago, is secretary.—The Academy of Physical Medicine will hold its annual meeting in Boston at the Hotel Statler, October 20-22.—The thirty-ninth annual meeting of the Association of Surgeons of the Southern Railway System was held in Knoxville, Tenn., June 16-18, with the following speakers, among others: Dr. Edward T. Newell, Chattanooga, on "Treatment of Fractures, Report of 11,000 Cases"; Thomas H. Hancock, Atlanta, Ga., "The Time to Amputate Crushed Limbs"; Wyatt H. Blake, Jr., Sheffield, Ala., "Treatment of Skull Fractures and Brain Injuries"; William Battle Malone, Memphis, Tenn., "Gas Gangrene," and Hubert A. Royster, Raleigh, N. C., "The Pressure Dressing."—Dr. William W. Francis, Montreal, Que., was reelected president of the Medical Library Association at its annual meeting in St. Paul recently. Mr. James Ballard, Boston, was made vice president and Miss Janet Doe, New York, reelected secretary. The 1937 meeting will be in Richmond, Va.

CANADA

Society News—Dr. Myron Metzenbaum, Cleveland, was a guest speaker at the meeting of the Ontario Medical Association in London recently. He conducted a clinic demonstrating a procedure for replacements of dislocations of the lower end of the septal cartilage in children and gave a paper on the subject.—Dr. Gordon C. Kenning, Victoria, was elected vice president and president-elect of the British Columbia Medical Association at the annual meeting in Vancouver in June and Dr. George F. Strong, Vancouver, was installed as president.—Dr. George Clingan, Virden, was elected president of the Manitoba Medical Association at its annual meeting in May.

FOREIGN

British Medical Association—The one hundred and fourth annual meeting of the British Medical Association was held in Oxford July 17-25, under the presidency of Sir James Barrett, Melbourne, Australia. On the provisional program were noted the names of several American physicians. Papers were presented by Drs. Lloyd D. Felton, Baltimore, on "Prophylaxis of Pneumonia"; Foster Kennedy, New York, "The Neuroses from a Neurologist's Point of View"; Gabriel Tucker, Philadelphia, "Inflammatory Tumors of the True Vocal Cords"; and Arthur J. Bedell, Albany, "Choroideremia." Dr. Royal Whitman, New York and London, was scheduled to open a discussion of "Treatment of Intracapsular Fractures of the Neck of the Femur" and Dr. Ralph M. Waters, Madison, Wis., one on "Cyclopropane." Prof. Robert J. Johnstone, professor of gynecology, Queen's University, Belfast, Ireland, was named president-elect and Sir E. Farquhar Buzzard, Oxford, was inducted into the presidency.

Society News—The fifteenth International Congress for Hydrology, Climatology and Medical Geology will be held at Belgrade, September 25-29. Subjects for discussion will be thermal treatment of diabetes, new problems in the biophysics of water, climate in the prevention and treatment of juvenile tuberculosis, and geology of the spas of Yugoslavia. Information may be obtained from Prof. Milutin Neskovic, 42/1 R. Nemanzina, Belgrade.—Dr. Anthony Bassler, New York has been appointed president and Dr. Martin E. Rehfuess, Philadelphia, vice president of the American delegation to the International Congress on Hepatic Insufficiency in Vichy, France, Sept. 16-18, 1937.—The third International Congress for Study of Light will be held in Wiesbaden, September 17, under the presidency of Dr. W. Friedrich Berlin. Subjects to be discussed are physical and biologic bases of phototherapy, light treatment in tuberculosis, use of light in pediatrics, internal medicine and other medical disciplines. The general secretary is Dr. H. Schreiber, Berlin NW 7, Robert Koch Platz 1.

The Prescribing of Hearing Aids

At a joint meeting of the Sections of Otolaryngology of the Royal Society of Medicine, Mr T E Cawthorne said that no branch of otology had received less attention than the prescribing of hearing aids, with the result that the deaf turned elsewhere, attracted by extravagantly worded advertisements, the cost of which was reflected in the price they had to pay for their appliances. No wonder that they were satisfied to sacrifice efficient performance for pleasing appearance. The vendors filled their pockets by flattering the patient's eye at the expense of his ear. A hearing aid was desirable when the hearing defect was such that, despite treatment, normal methods of communication were impossible or irksome. The complete solution of many complex problems presented by the correction of a hearing defect was not possible in the present state of knowledge, but the invention of the thermionic valve had so increased the amplification of sound that already a great increase in the efficiency of hearing aids had been brought about and it was not beyond the bounds of possibility that as good results would be attained in prescribing hearing aids as had been achieved in prescribing visual aids. Unfortunately there was not at present any standard of performance of hearing aids for the guidance of the otologist or the safety of the patient. The greatest service the otologist could render the incurably deaf was to guide him in the choice of a hearing aid.

Some unit of hearing loss must be used to facilitate understanding between the prescriber and the dispenser. At present the most favored unit was the decibel, which roughly represented the smallest increase in sound intensity appreciable by the normal ear. It was a logarithmic unit, i e., 10 decibels corresponded to a tenfold increase in sound intensity, 20 to a hundredfold, 30 to a thousandfold. The level for ordinary conversation was about 55 decibels. The method of estimating hearing capacity both for speech and for pure tones lent itself to accurate reproduction, so that improvement with an aid could be measured. The audiometer had the advantage over the tuning fork that its output could be raised kept constant or increased at will and was susceptible of accurate measurement. It was far quicker and far more accurate than the tuning fork for measuring hearing capacity for pure tones. In a speech test monosyllables should be used, each chosen to accentuate a different vowel or consonant. All patients with pure middle ear deafness could derive benefit from an aid. In deafness with less than 50 per cent of cochlear function the amplification required for an aid was such that its intensity would approach the upper threshold of hearing, and confusion and discomfort would result. The care and upkeep required for valve aids was often more than the patient could afford. A hearing aid department should be essential to every well equipped otologic clinic.

"The Holmes-Adie Syndrome"

At a meeting of the Medico-Chirurgical Society of Edinburgh, Prof Edwin Bramwell read a paper on a benign condition that is important because it is easily mistaken for syphilis of the nervous system. In the present state of knowledge an etiologic or pathologic terminology is impossible, so he proposed "the Holmes-Adie syndrome," because the two English neurologists mentioned were chiefly responsible for its isolation in 1931. In 1924 he saw a woman, aged 56, of whom it had been noted at the eye department of the Edinburgh Royal Infirmary that she had Argyll Robertson pupils. From there

she was sent to the department for venereal diseases, where it was found that the blood Wassermann reaction was negative and the cerebrospinal fluid normal. Professor Bramwell noted that the condition of the pupils was particularly interesting, both being large and immobile to light but contracting on convergence. The left eye on convergence slowly in the course of ten to fifteen seconds came down almost to pinhole size and then slowly dilated, reaching its ordinary size in a minute to a minute and a half. He had never seen anything like this before. The right pupil reacted normally on convergence and did not become nearly so small as the left. Ankle and knee jerks were absent. The immobility of the pupils to light and the absent knee jerks suggested syphilis, but three facts were against this diagnosis: the absence of other symptoms of tabes, the negative Wassermann reaction and the large pupils with the slow contraction of the left pupil on convergence and its still slower dilatation. Professor Bramwell indexed the case as a pupil abnormality with absent tendon jerks and did not commit himself to a diagnosis, but the probability of syphilis must have occurred to him, for he prescribed mercury and iodide.

To the peculiar pupillary reaction which this case exemplifies Holmes applied the term "the tonic pupil." In 1931 he read a paper at the Ophthalmological Society entitled "Partial Iridoplegia with Symptoms of Other Diseases of the Nervous System." Among fifty-four cases of partial paralysis of the pupil of unknown etiology, which he had observed, some of the tendon jerks were diminished or lost in nineteen. In all, one or both pupils were quite immobile to light. He concluded "In the present state of our knowledge a separation of those cases in which the tendon jerks are absent from those in which they persist is unjustifiable." Adie analyzed thirteen cases that had come under his personal notice and nine previously recorded in which the tonic pupil was associated with absent tendon jerks. He expressed the view that the tonic pupil when found all alone was a milder form of the same condition. He was the first to apply "benign" to the syndrome, because no further developments ever occurred. It seems that the syndrome is often mistaken for syphilis by those unacquainted with it and Professor Bramwell thinks that in former years he himself must have repeatedly made the mistake. Unlike nervous syphilis, it is much more common in women than in men. It is unknown to most clinicians because it has not received a name. Hence Professor Bramwell's suggested name for it. It does not appear to be very uncommon. It may be unilateral. Incomplete forms are seen in which tonic pupils, iridoplegia, ophthalmoplegia interna or absent knee jerks occur as isolated phenomena.

New Test for Carcinogenic Oil

The Manchester Committee on Cancer reports that a specification for mineral lubricating oils has been drawn up, which should reduce to a minimum the risk of the production of cancer in mule spinners and other workers. Dr C C Twort, director of the Cancer Research Laboratories, describes a new test for assessing the carcinogenic and dermatitic properties of mineral oils, which has the advantage of requiring only seven to ten days to complete. It consists in injecting a few drops of oil into an animal and subsequently recovering the oil for examination. If the oil is toxic, its physical characters will be altered; if nontoxic, they will remain unaltered.

The Institute of Medical Psychology

The Institute of Medical Psychology, which was founded in 1920, has expanded considerably. It has now twenty-two consulting rooms of which six were recently added, yet functional nervous disorders are so prevalent that it has always a long waiting list of patients. In 1925 the number of attendances of patients was 20,614, an increase of 3,828 over the previous year. The medical staff now amounts to sixty-nine, an increase of

eight, not counting those concerned with physical investigation. Patients with anxiety neurosis predominated and derived much benefit from the community life of the hostel. In the children's department more than 600 attended and much is being learned of the psychology of the neurotic child. An interesting feature is a museum of toys from all over the world. In order to deal more effectively with functional nervous disorders the institute has now acquired a site on which a hospital will be erected with accommodation for 100 beds.

The institute is a center of education in psychologic medicine and has a well equipped laboratory. The training course for physicians as specialists in psychotherapy covers two years. For the advanced investigation of psychopathology by members of the staff a series of study groups has been formed to deal with such conditions as personality types and sex perversions and disorders of childhood, as well as one for social workers and playroom supervisors.

A Loophole in the Social Insurance Law

The social insurance law in France permits the insured worker to select his own physician. This is not the case in some other European countries. There is a bureau to which employers and employees pay in equal amounts a premium based on the salary and civil status of the employee. When the latter is ill and is cared for by the physician he has selected, the fees of the medical attendant are paid by the patient, who is reimbursed by the bureau through which he is insured. In the May 31 issue of the *Concours medical* is an article by Paul Boudoin, the medicolegal editor, entitled

"Can a Physician Oppose Payment of Indemnity to the Insured if the Physician Has Not Been Paid?" In the case which forms the subject of the article, the physician was not paid by the insured worker and hence demanded that the bureau through which the worker was insured should pay for the medical services that had been rendered. The law states that in order that an insured worker should be indemnified for any medical expenses, his certificate of illness must be countersigned by the attending physician. The bureau ignored this requirement and reimbursed the insured who had not, as stated in the law, previously paid his physician. Boudoin gave as his opinion that as a matter of equity the physician had a right to sue the bureau for the amount of his fee. Unfortunately, the social insurance law contains clauses according to which the attending physician can hold the insured responsible only for medical services and that the local bureau assumes no obligations to pay the physician directly but in reimbursing the insured it supposes that he will immediately pay the attending physician. The moment that a physician signs the illness certificate of the insured the bureau has every reason to believe that the physician has been paid. In the case which formed the object of the query the bureau had reimbursed the insured even though the certificate had not been signed and the attending physician is powerless to collect his fee.

This is a serious loophole in the social insurance law.

Social Insurance Organization Establishes Diagnostic Centers

Some time ago Cibrie, secretary of the principal association to protect medical interests, warned the profession that unless diagnostic centers were established by organized medicine in association with the social insurance authorities the latter would do so independently. Cibrie's prediction has been verified and although a "center of control" already existed in Paris the *cassés* or *bureaux* which receive the premiums from the assured and their employers and, as called on, pay all medical expenses of the assured have now opened a "diagnostic center" at which

radiologic, serologic and other examinations are compulsory in order to receive maternity benefits. Cibrie states that this is only the first invasion of the field of organized medicine and that unless the latter shows itself willing to cooperate with the social insurance authorities they will go ahead heedless of all interference.

Meeting of Biologic Society

At the May 16 meeting of the Société de biologie of Paris, Loeper and Lesure reported that, as the result of their investigations, tyramine and similar substances are to be found in increased quantities in the serum in cases of hypertension. This increase is less absolute than relative in relation to the hypotensive bases, which are derivatives of histamine. It would appear as if, in pathologic cases, an imbalance could occur in the relation of tyramine and histamine, substances that are antagonists.

REFRIGERATION FOR THE CONSERVATION OF VIRUS

Lepine showed that it is of importance, in order to conserve virus of neurotropic type, to use as a substitute refrigeration (to minus 10-20 C.) of emulsions or viscera containing a virulent virus in place of glycerin, which weakens the virus. Even a virus that offers little resistance to glycerin can be conserved by such a refrigeration. To attain its full effect, the refrigerated virus should be kept in as dry a condition as possible and protected from contact with the air. Refrigeration is a simple and efficacious method of conservation of a virus.

EFFECTS OF EPINEPHRINE ON THE CEREBRAL CIRCULATION

The direct microscopic observation of the vessels of the cerebral cortex in dogs was rendered possible for Cachera and Fauvert by utilizing a transparent (glass) vase placed in a trephine opening in such a manner as to exclude the air. They were able to secure a number of photomicrographs which permitted them to measure accurately the caliber of the cerebral vessels and to graph the blood pressure in and volume of the brain. Thus a comparison can be made between the caliber of the cerebral vessels and the level of the blood pressure at the same time. An analysis of the vasomotor reaction of the brain is thus made possible. When epinephrine was administered intravenously or into the carotid, the following results, which confirm recent work of other investigators, were obtained: 1. Dilatation of the cerebral arterioles (plus 10-45 per cent). 2. Slightly increased caliber of the veins (plus 10-20 per cent). 3. Increased volume of the brain. The vascular dilatation is not always immediate, however, no initial vascular constriction was ever observed. This vascular dilatation seems to be passive, closely related to the variations in general blood pressure, but there is no close proportional relation between the dose of epinephrine that had been given and the generalized rise in blood pressure, on the one hand, and the degree of cerebral vascular dilatation on the other. The latter can persist a long while after a drop has occurred in the hypertension due to the epinephrine.

Arteriectomy for Volkmann's Contracture

At the April 1 meeting of the Académie de chirurgie of Paris two cases were reported by Leveuf, one for Salmon the other for Perrot in which arteriectomy was performed for the syndrome known as Volkmann's contracture, in both cases following supracondylar fracture of the humerus. In Salmon's case a boy aged 14 had been seen on the day after the accident. He was unable to move his hand and the fingers were flexed. Only slight extension movements were still possible and there was complete anesthesia over the skin areas supplied by the median and ulnar nerves. Immediate operation was contra-indicated on account of the presence of bullae on the skin of the forearm. Reduction of the fracture was carried out under

fluoroscopic control. Electrical examination on the seventh day revealed marked diminution in the excitability of the median, ulnar and radial nerves as well as in the muscles of the forearm. At operation, twenty-seven days after the accident the brachial artery and median nerve at the level of the front of the elbow were found embedded in a mass of scar tissue. Four centimeters of the artery was resected at this level. Examination of the specimen revealed that the lumen of the artery was completely occluded by an organized clot. Following this operation, temporary improvement occurred in the form of better circulation in the hand and less marked flexion deformity of the fingers for forty-eight hours. The boy was not seen again until six weeks later. At this time he could move the fingers better, but the hand was cold. The nerves of the forearm showed a hypo-excitability to electrical stimulation and there was a reaction of degeneration in the muscles of the forearm. No improvement having followed the use of electricity and massage during the next six months, three centimeters of the shafts of the radius and ulna was resected. This was followed by the boy's being able to extend the fingers completely. A year after the accident, all active movements of the wrist and fingers could be executed. Only a slight limitation of extension of the wrist and of flexion of one of the fingers persisted. With the exception of slightly decreased electrical excitability of the extensor muscles, all nerve and muscle reactions are now normal.

In Perrot's case, a boy, aged $2\frac{1}{2}$ years, had sustained a supracondylar fracture of the humerus with marked displacement of fragments. Reduction was done under fluoroscopic control and a well padded splint applied. Eight days later the hand and forearm were found to be cold and edematous, the radial pulse was imperceptible and the child was unable to move the wrist or fingers. The fracture area was exposed the following day and the brachial artery found embedded in fibrous tissue and raised up by the upper fragment. The median nerve was intact. Three centimeters of the obliterated (thrombosed) artery was resected. Half an hour after the operation the circulation in the hand seemed to be reestablished and the following day some movement of the fingers was possible. This improvement lasted only forty-eight hours so that eighteen days after the operation the typical Volkmann deformity of the hand was marked. This condition, associated with anesthesia in the skin area supplied by the ulnar nerve, and marked electrical changes in the muscles of the forearm and thumb were still present three and a half months after the operation. The child was not seen again by Perrot until a year after the accident. At this time the hand appeared normal.

Infantile Acrodynia in France and Other Countries

At the May 5 meeting of the Académie de médecine an exhaustive report was made by Péhu and Boucomont of the distribution all over the world of infantile acrodynia. A complete statistical study is at present impossible because the disease is not always recognized. In addition, the health authorities have as yet not demanded its declaration. In France it is found in all portions but in central France it occurs frequently. This is true also of Belgium, the Netherlands, Great Britain, the northeastern section of Switzerland and southwestern Germany. Few cases have been observed in Austria, Hungary, the Balkan countries, Italy, Spain and Portugal. A striking fact is that it does not seem to occur in the Scandinavian countries. Outside of Europe one may cite Australia and the United States as reporting a large number of severe cases. The distribution does not seem to follow any geographic or climatic laws. The disease is especially common in small rural communities. The larger centers of population appear to be relatively immune. Acrodynia does not occur in epidemic but rather in sporadic form.

Does Traumatic Lumbago Exist?

The question whether there is a traumatic form of lumbago has been the subject of a suit against an insurance company which was willing to pay an indemnity, if it could be shown that a lumbago could be regarded as an industrial accident. There is so much opportunity for malingering in such a clinical condition as lumbago that insurance companies in France have maintained that the claimant must prove the direct relation between the accident and the lumbar pain complained of.

In 1933, one of the departmental appellate courts held that the effort, even ordinary, which an employee made in carrying out his work can give rise to an injury and that the latter must be considered as an industrial accident. The employer is thus obliged to prove that a given lesion such as a lumbago is not the result of an accident incurred during the performance of ordinary tasks. A well known French medical expert declares that traumatic lumbago is due to a muscular rupture and that the resultant pain would be so severe as to cause the individual to cease work immediately and to be confined to bed for a variable period. Hence, if before the accident there was no interruption of work and if witnesses can affirm that a claimant was obliged to discontinue his task immediately in attempting to immobilize the lumbar region, there was a direct cause and effect relation unless it could be proved by other means that no such accident was possible in the normal course of the duties of the worker.

Hemolytic Familial Icterus

At the May 15 meeting of the Société médicale des hôpitaux of Paris, Debré, Lamy, See and St Schrameck reported their observations, in nine families, of twenty-five cases of congenital hemolytic icterus. The disease frequently presents a clinical picture which differs from that of the classic descriptions. For example, several of the patients had only a subicteric hue of temporary character and only after considerable questioning could the patient remember having been slightly jaundiced. Some have never been icteric or subicteric. This was true of five of the twenty-five cases. The anemia, although more constantly observed than the icterus, may also be absent. Most frequently the red blood count is between 3,500,000 and 4,000,000. Only once was a red blood count less than 3,000,000. Splenomegaly was found in all the twenty-five cases.

These variations illustrate the polymorphism of a disease which at times presents as the chief sign a splenomegaly, at others a chronic icterus and finally a splenic anemia. The "formes frustes," recognized only after a systematic research into the family history, as a result of finding a moderately enlarged spleen, are certainly frequent. Several such cases have been discovered in nurslings and older children.

Certain hemolytic stigmas do not have the importance that is usually ascribed to them. This is especially true of the decreased resistance of the red blood cells toward hypotonic solutions. This finding is often lacking. On the other hand an increased bilirubin content of the blood can be regarded as the most accurate index of the hyperhemolysis. The latter is usually accompanied by evidence of a compensatory hyperactivity of the bone marrow in the form of an increased number of reticulocytes, as the myelograms (obtained by puncture of the sternum) reveal. The evolution of the "hemolytic disease" is often interrupted by acute attacks of biliary colic and of deglobulization. The latter are especially to be dreaded. The authors observed this complication in four children, seldom in adults. These acute attacks of deglobulization present the following clinical picture: high temperature, tachycardia, splenomegaly with or without hepatomegaly, rapid deglobulization so that the number of red blood cells reaches the low figure of a million, marked pallor and a soft systolic murmur over the heart area. As a rule the attack lasts only from twelve to fifteen days. At times the attacks assume a subacute character.

Other complications observed by the authors are cardiac insufficiency, corneal infiltrations and disturbances in development, i. e., in weight and height.

On account of its polymorphism, the disease often remains unrecognized unless a careful inquiry is made as to similar cases in the family of the patient. Many acute hemolytic anemias, splenic anemias of the Banti type and supposedly acquired hemolytic anemias are in reality cases of the 'familial hemolytic disease,' according to the authors. The disease is constitutional and familial, being transmitted in accordance with the mendelian laws, and it bears no relation to syphilis. The only treatment is splenectomy, and this should be done even in children.

In the discussion, Noel Fiessinger stated that one can find in the family of such patients a splenomegaly without icterus and without anemia. It is the splenomegaly which is hereditary, hence he would suggest calling the disease 'familial hemolytic splenomegaly' instead of 'congenital hemolytic icterus.'

Chabrol endorsed the view that the essential feature is the splenomegaly. The globular fragility is a secondary factor. Certain patients can live for years and the condition be diagnosed as acquired hemolytic icterus, the real diagnosis 'congenital icterus' never being suspected. Splenectomy is indicated if the anemia is progressive and also if there are recurrent attacks of severe right upper quadrant (biliary colic) pain.

New Fellows of Academie de Chirurgie

The following have been honored by election as fellows of the Academie de chirurgie: Professor d'Arsonal of the College de France, Leclanche, vice president of the Academie des sciences, the roentgenologist Antoine Beclere, and Claude Regaud, professor at the Institut Pasteur.

Joint Congress of "the New German Medicine" and Internal Medicine

At the end of April the joint congress of the National Cooperative Association for New German Medicine and the German Society of Internal Medicine took place as scheduled at Wiesbaden, a city which the internists for decades have made their gathering place. This joint congress had been looked forward to as of great historical significance, especially since the national führer of medicine, Dr. Wagner, had asserted that in future every German physician should resort to tested and approved Nature Cure procedures as readily as to any other therapeutic or prophylactic measure. Wagner has also stated, however, that "we do not blink the fact that when entrusted to the ignorant and the unskilled the mighty forces of nature may conceivably work as great a mischief as would the incorrect prescription of a medicament, for example." As a result the attendance at this congress was unusually large, all medical and political ranks of National Socialism in any way concerned being represented. When the internists and the Nature Cure men met in joint session on the third day, the attendance was estimated at 2000 persons, an almost unprecedented figure. But, as a leading German medical weekly regretfully notes, many of the older professors who are usually most regular in their attendance men who might be called the guiding spirits of past congresses at Wiesbaden, were absent. Professor Schwenkenbecher of Marburg presided over the internists while the National Cooperative Association had as its chairman Professor Kötschau of Jena, head of the Biologic Policlinic and a former pupil of Professor His at the University Clinic in Berlin.

The contrasting opinions to be reconciled at Wiesbaden were various and sundry. As the *Deutsche Arztzeitung* expresses it

the chief differences discussed were those existing between physician and public, between academic medicine and the biologic movement, between specialized science and knowledge and doctrine intuitively arrived at. This congress served to elucidate many strange things.

On the first two days the Reichsarbeitsgemeinschaft held sessions. Presiding officer Kötschau stressed first of all that the organization, far from being a rallying point of irregular medicine, is just as dependent on scientific medicine as so-called academic medicine, despite the fact that the new medicine includes therapeutic methods that have for centuries enjoyed wide usage among the people and are of proved worth. The views of many among the internists and the views of the Nature Cure physicians were in many respects similar. The permeation of the entire medical profession with the ideology of a biologic medicine has been made necessary by political expediency. Under the circumstances the congress should be purely informative in character, its objective should be to acquaint the medical profession as a whole with the new doctrines. A free interchange of ideas can lead to symbiosis and synthesis and ultimately to a unified new German medicine. Three years of National Socialistic government has already made possible the removal of a whole mass of prejudice, and the dawn of a new era in German medical science has been recognized. The way now lies open for the composition of all differences.

As might have been expected, the papers expressed for the most part the views of the exponents of "Biologic Therapy" and were supposed to supply scientific bases and substance to therapeutic methods that owe their practical success largely to empiricism. One author, for example, sought to illustrate the relation of paracelsian doctrine to the German medicine. Paracelsus, he said, considered all medical activity as rooted in the folk and in the soil. The Jena anatomist Professor Boker explained in a paper on "Morphologic Bases of the Biologic Theory of Medicine" that academic and biologic medicine differ not so much with regard to the therapeutic methods employed by practitioners, but more radically with regard to basic theoretical concepts. The difference might be epitomized as the opposition of Mechanism to "Holism" (entirety, a synthesis of mechanistic and vitalistic elements), of causal analysis to causal synthesis, of passive-technical events to active animated reactions. Academic medicine is based on the chemico-physical or mechanistic theory, the new movement while not akin to an extreme vitalism, may lead to a superordinated Holism, which would reckon vital phenomena as active processes closely bound to passive processes.

Among other communications by adherents of this movement, that of G. Wegener should be mentioned. Wegener is director of the National Federation of Societies for Life and Therapeutic Methods in conformity with Nature and is not a physician. He spoke, of course, in behalf of the popular medicine movement and asserted that Nature Medicine had been misunderstood—on the one hand by presumptuous persons who had not wished to believe that nature can heal (?) and on the other by "those charlatans and false prophets who would hawk their Nature Medicine as if it were merchandise at a fair." One seems always to forget "the souls of German men," which 'possess a lighter and finer sensitivity perhaps than those of any other people on earth.' 'German man, in his unspoiled naturalness experiences an emotional element in healing, a feeling that the hand of a true physician and a pair of soulful eyes from which shine forth a noble spirit are of greater worth than a plenitude of physical and chemical apparatus.' The foregoing are excerpts from the learned address of the Director of the entire German Popular-Healing Movement delivered at a medical convention held under the special protectorate of the national führer of medicine. Further quotations from the

same speech exemplify even more graphically the implications of the philosophy of the new school. "It is inimical to the cooperation between doctor and people that the tiny microscopic lamp should so often be confounded with the mighty Sun,

the objectives of the Popular-Healing Movement are these: to instruct in matters of health and hygiene, to point out the paths to be followed and to disseminate necessary knowledge so that self help and the organism's defense mechanism can be supplemented and first aid measures carried out before the arrival of a physician. The physician and the recognized healing practitioner both stand ready to treat and to cure disease."

Additional speeches bore the imprint of the same train of thought. One doctor set forth a new type of hospital procedure: the patient should be repeatedly advised and persuaded that he shall quit the hospital both internally and externally restored to health, such a suggestion may help to bring about a "constitutional alteration." Another speaker believed that since the weltanschauung and leading practical principles of New German Medicine must parallel the development of National Socialism, popular medical orators should receive special training in schools of elocution. Thousands of physicians would thus find promising fields of activity as medical instructors in hygiene and as *führers* of the various Nature, Kneippian and Reformed organizations.

There were in addition the expected papers on the integration of homeopathy with New German Medicine and on the value of medicinal herbs. Here at last were topics amenable to being discussed by scientifically trained physicians. None of these papers, however, presented anything fundamentally new. More specific problems were next discussed. Dr. Bottenberg of Frankfurt-on-Main, already well known for his publications in the field of "biologic therapy" and more of a critic than many others, took this opportunity to point out that the unrestricted use of sweatings, venesections, blood leeches and so on must needs have a deleterious effect on the patient. This warning indicates how widespread the use of these methods, many of them snatched from oblivion, has become in present-day Germany. Further papers dealt with questions of psychic import in the well known manner.

A paper on the function of biologic dentistry told of a startling increase in dental and maxillary disturbances as disclosed by group examinations among the Hitler youth and other young peoples organizations. Here the problem is to overcome the predisposition to caries and parodontitis. There followed discussions of several clinical topics such as bronchial asthma, rheumatism, passive aortic gymnastics, physical exercise and radon emanation treatment.

The third day of the gathering was given over to the joint session with the internists. In an introductory address Professor Schwenkenbecher of Marburg delineated tactfully the tasks confronting the joint assembly and recognized the *reichs-arbeitsgemeinschaft* as a scientific body. He pointed out that turning away from the exclusively natural scientific concept is for the understanding of the vital processes tantamount to a rejection of purely materialistic philosophy, such a trend has suddenly received new significance since the National Socialist revolution. Physicians of the so-called academic medicine are many times lacking in first hand knowledge and ability to apply physical methods. Fundamental differences exist particularly with regard to dietetics, the abundance and variety of dietary methods, most of which are carefully tested and which strive to adapt themselves to the individual case, form quite a contrast to the only slightly varying raw vegetable diet of Nature Cure Medicine. The work of the association must not be restricted to speeches and debates: there must be mutual clinical activity, thoroughgoing mutual examination of methods and mutual acquaintance with the other fellow's way of think-

ing. Even when these things are obtained it will still be difficult to determine whether or not a course of treatment will produce the desired result. The most diverse results are possible, owing to idiosyncrasies of the patient selected for a test, to differences in experimental methods themselves and to the method used to evaluate the results. Medical tradition, moreover, hinders a proper evaluation. Cooperation ought not, however, to lead to a hasty superficial equalization of the differing *anschauungen* and methods. Precisely in differentiation are to be found those forces which are indispensable for mutual stimulations and reciprocally fruitful contacts.

In contrast to the prudent formulations of Schwenkenbecher was a forceful, aggressive speech by Professor Kötschau on "The Place of Preventive and Other Treatment in New German Medicine." The acceptance of a scientific principle is justified only after its practical utility has been authenticated. On a basis of this essential utility, history delivers its verdict. This justification of a scientific principle may well depend on how deeply it is rooted among the people. "We of today realize," said Kötschau, "that the dream of an absolute, supposititious, objective natural science and medical science has been dreamed out." The younger medical men, he continued, are turning from the misuse of exact natural science in biology and in medicine. Contemporary scientific medicine is by no means to be rejected, but, on the other hand, the scientist must guard against a priori rejections of methods and ideas which are alien to his accustomed train of thought. One of the most important of all therapeutic procedures is, from the standpoint of the strictly scientific school, incomprehensible and inexplicable: the process of natural healing. Both health and disease are to be understood as manifestations of the hidden, ever active healing forces of nature. By prophylaxis, that is, activity in conformity with nature, the need for therapeutic measures should be less frequent, for treatment is usually first instituted when a disturbance is already manifest. New German medicine is simple, self comprehensible and natural, it can never become alien to the people (this last is a reproach, which has been directed at academic medicine by adherents of the new doctrine with increasing frequency.)

A middle position between the points of view of these two chairmen was taken by the national *führer* of medicine, Dr. Wagner, the man responsible for the holding of this joint assembly.

The more interesting portions of his discourse are paraphrased. It is desirable that in future a difference between "biologic" and academic physicians shall no longer be recognized. The ideal for which all should strive is that of the general, trained family doctor, the German people's physician whose principal concern is the actual needs of his fellow countrymen! When the confidence of those fellow citizens is again won, then we shall approach a problem the solution of which is an imperative necessity, that of unrestricted therapeutic activity. All men concerned are agreed on one point, that the present unrestricted therapeutic activity is incompatible with the *anschauung* and requirements of National Socialism. Accordingly this too great freedom with regard to healing must be ended as soon as possible. This also represents the wish of the healer himself, and certain concessions must in the future be made for a selected group of these practitioners (who might more accurately be termed quacks, since they are certainly not physicians and have had no regular course of training).

This talk of a finally imminent suppression of the independent healer or quack whose pernicious doings have been reported more and more frequently in recent years was Wagner's reciprocal gesture of gratitude for the recognition of the Nature Cure physicians by scientific medicine through the latter's most representative German group: the Society of Internal Medicine. The internists were fully aware of this fact.

Of like interest were the remarks of the deputy to the führer of medicine, Dr. Blome, who, speaking on postgraduate medical studies, attempted to give both academic and Nature Medicine their due. It is unfitting, he declared, that certain cliques should make it their business to decide onesidedly what direction medicine should follow. How frequently it happens that specialists who consider themselves authorities in their proper fields and perhaps are so in fact may be virtually ignorant of what their colleagues in other fields are doing. Continued Blome, "There is no denying that there exists today an exaggerated specialism which the average German rejects instinctively as foreign to his nature. American methods and anschauungen certainly must not prevail in Germany. This inability to think in any other terms but those of organs and systems of organs frequently causes the specialist to become narrow, short sighted and, as a consequence, intolerant of others." The important function of pure science should be fully appreciated but the direction of sanitary affairs is the duty not of the scientist but of the National Socialist movement, of the party. It is of paramount importance that the family physician whose general training is excellent be restored to the people and that cliques of mediocre specialists, such as exist today, be put out of commission. The extremists of both groups, the recalcitrant dogmatic academicians together with the nature cure monomaniacs, shall be left out of the picture. Nor must any one think for a minute that Nature Cure Medicine is presuming to dictate to academic medicine. A synthesis of the two schools must be accomplished. The foregoing explanations are of particular significance, falling as they do from the lips of one who controls compulsory postgraduate study throughout Germany.

The Berlin internist Professor Siebeck next spoke on the treatment of cardiac insufficiency.

Finally, the two assembled bodies passed a joint resolution which requested that a strictly scientific but unbiased investigation and further development be made of all natural therapeutic procedures which seem to promise favorable results. The joint session was forthwith adjourned. Subsequently the internists alone held a further session. Taken all in all, the joint assembly occasioned the expression of many opinions which are of interest even for those of us who cannot subscribe thereto and, in any case, it permitted a good glimpse of the road that German medical science of today is perforce traveling.

BELGIUM

Can Incurability be Determined in a Criminal?

Dr. Vervaecke, who has studied the problem whether or not incurability can be determined in a criminal, questions the efficacy of the classic methods of treating criminals. He doubts whether these procedures exercise any appreciable influence on the subjects. The better to inform himself on the question the author made use of some Belgian statistics on recidivism. In the year 1924, out of 91,597 offenders sentenced, 17,299 were recidivists more than half of whom had repeated the same type of offense which had brought about the previous convictions. Two divergent views are taken of recidivism. Jurists and prison officials generally hold the imperfect character of the penal system at fault while medical men look on the recidivist as a victim of biologic predispositions. Vervaecke, after thirty years' experience favors the second point of view, he recognizes not only the influence of predispositions but that of the circumstances as well as having caused the misdeed. World predispositions are frequently observed in recidivists of the group studied only 3 per cent possessed more than average intelligence and these had been convicted on frauds and confidence games.

There are no certain indications for prognosis of incurability. Most significant from the author's point of view are the number of offenses committed, repetition of an offense after a short lapse of time, the culprit's reaction on learning what is to be his punishment, and so on. Anthropologic examinations yield interesting indications but no certain diagnostic method. Neither the large number nor the gravity of the indications leads to a pessimistic conclusion. A change for better or for worse may intervene, caused by changing qualities within the criminal and by that which Vervaecke calls "slackened psychologic development," that is, age, emotivity, and sequels of contagious diseases such as typhoid and encephalitis, all factors capable of offering a certain resistance to his inclination.

The foregoing statement suggests that recidivists are frequently afflicted with biologic anomalies. The author quotes statistics from the Merxplas asylum, an institution especially designed for the care of recidivists in Belgium, in which 90 per cent of the inmates presented physical abnormalities or were afflicted with psychopathic, moral and emotional defects. None of these defects, however, can lead to a determination of definitive incurability.

Investigation of the Etiology of Epilepsy

Mr. Laruelle discussed before the Medicosurgical Society of Brabant an investigation of 375 cases of epilepsy which had led him to conclude that no essential difference exists between general epilepsy and partial epilepsy. Of 375 patients, most of whom had been listed as presenting essential epilepsy, Laruelle was able to establish the etiology in 62 per cent. In the first rank, one finds a notable proportion of heredoalcoholic persons (13 per cent). The alcoholism was established in three generations. The second most important etiologic factor was cranial, including obstetric, trauma. The relation of the traumatism to the epilepsy is often most difficult to establish, modifications in the form of the ventricles at certain points are here of great value, particularly cicatricial retractions secondary to arachnitis. Heredo-epilepsy was determined in a number of cases. In other cases the disease arises in heredo-syphilis. Infantile eclampsia, however, must not be placed on a level with epilepsy. Eclampsia is due in part to cerebral conditions, since at that particular epoch the brain is not held in check like that of an adult. Cerebral tumors are responsible for convulsive reactions appearing in 20 per cent of the cases. Humoral examinations conducted by Laruelle failed to show any constant metabolic variation in epilepsy. On the other hand, great instability of the humoral equilibrium was encountered, attributable perhaps in addition to the irritability of the cortex to an alteration in the region of the floor of the third ventricle or median diencephalon. Epilepsy and migraine present many common characters, cerebral angiospasm and allergic factors, for example. Since epilepsy is so prevalent (more than one case for each 400 persons) a thorough etiologic investigation should be undertaken in each instance. This may lead to a therapy based on causal factors. If need be, one should even resort to surgical exploration.

Antidiphtheritic Immunity in the Congo

It is generally conceded that diphtheria is nonexistent in the Belgian Congo. Van Slyke, however, has called the attention of the Belgian Society of Tropical Medicine to his investigations among natives from the region of the rivers Lomami and Kasai. When the Schick reaction test was given to forty-four healthy adults, 56.8 per cent of the subjects showed a negative reaction, evidence of an anterior immunization. Accordingly an attenuated type of diphtheric infection would seem to be present among the aborigines of the Belgian Congo so mild as ordinarily to pass unnoticed but leaving its imprint on the person.

Marriages

RICHARD B GREENE Philadelphia, to DR LUCILLE ELISE TUCKER of Reading, Pa., in New York, June 24

JOHN PHILIP GRAHAM, Galesburg, Ill. to Miss Eleanor Hegy of San Jose, Calif., in New York, June 13

LAWRENCE BREITBART, Flushing, N Y, to DR. SARA YAMPOLSKY of Edmonton, Alta., Canada, July 1

JACKSON T RAMSAUR, Cherryville, N C, to Miss Lucile Byrd Draughon of Durham, May 30

LINWOOD MALONE GABLE to Miss Martha S Bidaman, both of St Petersburg, Fla., June 27

NORMAN O SPIKES Durham, N C, to Miss Vera B Baldwin of Atlanta, May 4

RICHARD GLENN HAHN to Miss Margaret Miller Landes, both of Bath, Pa., July 15

HUBERT E BONEBRAKE to Miss Mildred Reinhart, both of Portland, Ore., June 3

MORRIS W GREENBERG to Miss Sarah Freedman, both of Brooklyn, recently

BERNARD A. KAMAI to Miss Mary Dailey, both of South Bend, Ind., May 25

Deaths

Daniel S Dougherty @ New York, University of the City of New York Medical Department, 1884, member of the House of Delegates of the American Medical Association from 1927 to 1928, from 1930 to 1932 and in 1935, since 1916 secretary and since 1929 director of activities of the Medical Society of the County of New York, secretary of the Medical Society of the State of New York since 1925, and at the recent annual session of the society made secretary emeritus, for many years professor of otology at the New York Polyclinic Medical School and Hospital, formerly secretary of the New York Academy of Medicine, member of the American Laryngological, Rhinological and Otological Society, fellow of the American College of Surgeons, attending otologist to the New York Polyclinic Medical School and Hospital, consulting otolaryngologist to the City, People's Midtown, West Side, and Jewish Memorial hospitals, New York, Nyack (N Y) Hospital and the Long Beach (N Y) Hospital, aged 75, died suddenly, August 4, at his summer home in Nanuet, N Y

Harry Osgood Spalding, Hingham, Mass Boston University School of Medicine, 1897, member of the Massachusetts Medical Society, the American Psychiatric Association and the New England Society of Psychiatry, assistant in materia medica from 1900 to 1904, and instructor and associate professor of clinical psychiatry at his alma mater from 1912 to 1919 assistant superintendent of the Norwich (Conn) State Hospital from 1904 to 1912, formerly superintendent of the Westboro (Mass) State Hospital and the Wiswall Sanatorium, Wellesley, aged 65, died, May 10, in the Massachusetts Memorial Hospital, Boston, following an operation for adenoma of the prostate

Herschel Porter Hamilton @ Omaha University of Louisville (Ky) Medical Department, 1887, fellow of the American College of Surgeons, formerly professor of principles and practice of surgery and clinical surgery at the John A Creighton Medical College, chief of staff emeritus Evangelical Covenant Hospital, aged 76, died, May 28, of angina pectoris and coronary sclerosis

Alberta Sylvia Boomhower Guibord @ Newton Mass Boston University School of Medicine, 1899 member of the American Psychiatric Association and the New England Society of Psychiatry, at one time instructor in psychotherapeutics at her alma mater, psychiatrist in charge of the School Clinic, Boston State Hospital and consultant to the New England Hospital for Women and Children aged 62, died, May 27, of lobar pneumonia

Walter Byrd Pollard @ Winton N C University of Pennsylvania Department of Medicine Philadelphia 1899, past president and secretary of the Hertford County Medical Society, county health officer, member of the medical examining board during the World War and volunteered for medical service overseas aged 61, died, May 16, of chronic myocarditis and mitral regurgitation

Stewart McKee, Leavenworth, Kan, College of Physicians and Surgeons, Keokuk, Iowa, 1895, member of the Kansas Medical Society, past president of the city board of education, at one time city and county physician formerly on the staff of the U S Penitentiary Hospital, aged 75, died May 5, in St John's Hospital, of an infection following a prostatectomy

Seth Bachman Kistler, Nanticoke, Pa, Hahnemann Medical College and Hospital of Philadelphia 1928, member of the Medical Society of the State of Pennsylvania on the staff of the Wyoming Valley Homeopathic Hospital Wilkes-Barre, aged 31, died, May 15, in the Hahnemann Hospital, Philadelphia, of gastro-intestinal hemorrhage

J Carl Schmuck, Lawrence, N Y University of the City of New York Medical Department, 1882, for many years bank president and health officer of Lawrence, formerly on the staffs of the Nassau Hospital, Mineola, and St Joseph's Hospital Far Rockaway, aged 77, died, May 21, in Atlantic Beach, of diabetes mellitus and coronary thrombosis

Lester Graham Miller, New Orleans, University of Tennessee College of Medicine, Memphis, 1917, acting assistant surgeon U S Public Health Service, connected with the U S Quarantine Station of Algiers, aged 46, was killed, May 26, when he fell into the river as he was preparing to leave a steamer

Hiram Holden, Trenton, Mich, Michigan College of Medicine, Detroit, 1883, Bellevue Hospital Medical College, New York, 1890, at one time a druggist, formerly village president and president of the board of education aged 80, died, May 23, in the University Hospital, Ann Arbor, of bronchopneumonia

Foster Reed Winn @ Alvin, Texas, Marion-Sims College of Medicine, St Louis, 1896, past president of the Brazoria County Medical Society, veteran of the Spanish-American and World wars, for many years president of the school board, aged 66, died, May 5, in St Mary's Infirmary, Galveston

Charles Sidney Tate, Ramseur, N C, Baltimore Medical College, 1893, member of the Medical Society of the State of North Carolina, president of the Randolph County Medical Society, formerly county coroner, member of the local school board and county board of health, aged 72, died, May 25

Thomas Scudder Winslow, New York, Columbia University College of Physicians and Surgeons, New York, 1913, member of the Medical Society of the State of New York served during the World War, aged 52, director of the clinical laboratory of the Roosevelt Hospital, where he died, May 28

Richard Hayes Meagher, New York, Cornell University Medical College, New York, 1927, assistant professor of surgery at his alma mater, member of the American Psychiatric Association, assistant attending surgeon (neurosurgery), New York Hospital, aged 37, died, May 27, of heart disease

Carl George Zeidler, Belleville, Mich, Michigan College of Medicine and Surgery Detroit 1905 also a minister, formerly president of the village of Belleville, justice of the peace and health officer, aged 66, died May 24, in St Joseph's Mercy Hospital, Ann Arbor, of bronchopneumonia

John Pope Stewart, Attalla, Ala., Medical College of Alabama Mobile, 1885 member and life counselor of the Medical Association of the State of Alabama, past president of the Etowah County Medical Society formerly mayor of Attalla, aged 77, died, May 18, of myocarditis

Willmert Paul Laue, Santa Monica, Calif, Saginaw (Mich) Valley Medical College 1903, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1908, at one time a practitioner in Gary and South Bend, Ind., aged 58, died, May 2

Lee Monte Sankey, Jeannette, Pa Cleveland Homeopathic Medical College, 1908 fellow of the American College of Surgeons, served during the World War, member of the surgical staff of the Westmoreland Hospital, Greensburg, aged 54, died, May 14, of coronary thrombosis

Robert McWilliam O Neal, Santa Monica Calif College of Physicians and Surgeons of San Francisco 1904 served during the World War aged 56 on the staff of the Santa Monica Hospital where he died May 1 of carcinoma of the bladder with metastases

John Joslyn Kelley, Burr Oak Mich, Hahnemann Medical College and Hospital, Chicago 1900, served during the World War, for many years member of the board of education, aged 60 on the staff of the Sturgis (Mich) Memorial Hospital, where he died May 22

John Montgomery Randolph ☉ Rahway, N. J. University of the City of New York Medical Department, 1888, member of the board of education, for many years on the staff of the Memorial Hospital, aged 69, died, May 17, of cerebral thrombosis

John W. Sosbee, Stroud, Okla., College of Physicians and Surgeons, Dallas, 1904, member of the Oklahoma State Medical Association, past president of the Lincoln County Medical Society, aged 59, died suddenly, May 21, of coronary thrombosis

Samuel Dwyer Henry ☉ Excelsior Springs, Mo., Kansas City (Mo.) Homeopathic Medical College, 1894, past president of the Clay County Medical Society, on the staff of the Excelsior Springs Sanitarium and Hospital, aged 76, died, May 23

Emanuel F. Snyder ☉ Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898, aged 65, formerly on the staff of the Michael Reese Hospital, where he died, May 8, of coronary thrombosis

John Frederick Pritchard, Manitowoc, Wis., Rush Medical College, Chicago, 1871, member of the State Medical Society of Wisconsin, for many years member of the school board, aged 89, died, May 17, in the Holy Family Hospital, of senility

Samuel Engle Lee ☉ Greenville, S. C. University of Maryland School of Medicine, Baltimore, 1911, formerly superintendent of the Greenville County Sanatorium, aged 56, died, May 17, in Mountain Lake Park, Md., of coronary thrombosis

Kristian Henrik Egede Nissen, Minneapolis, Kongelige Frederiks Universitets Medicinske Fakultet, Oslo, Norway, 1888, formerly member of the state board of health, aged 72, died, May 7, of congestive heart disease and arteriosclerosis

William Ebenezer Waugh, London, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1872, bursar and for many years a member of the teaching staff of the University of Western Ontario, aged 85, died, May 25

Sidney Addison Sumbly, Saginaw, Mich., Howard University College of Medicine, Washington, D. C., 1930, member of the Michigan State Medical Society, aged 30, died, May 11, in the Saginaw General Hospital, of pneumonia

James Marcus McDavid, Memphis, Tenn., Kansas City College of Medicine and Surgery, 1919, at one time health officer of West Helena, Ark., and coroner of West Memphis, aged 49, died, May 10, of pneumonia

Francis W. Willard, Chicago, Marion-Sims College of Medicine, St. Louis, 1891, also a dentist, aged 70, died, May 14, in the Frances E. Willard Hospital, of diabetes mellitus and acute dilatation of the heart.

Thomas Richard Stack, Cleveland, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1888, at one time county physician, aged 67, died, May 8, of cerebral hemorrhage.

Edward Louis Schreiber, Milwaukee, Wisconsin College of Physicians and Surgeons, Milwaukee, 1904, on the staff of the Wisconsin General Hospital, aged 57, died, May 14, of a skull fracture received in a fall

John Joseph Healey, Providence, R. I., Harvard University Medical School, Boston, 1909, served during the World War, aged 53, died, May 4, of hypertension, chronic nephritis and cerebral hemorrhage.

Armand J. Prudhomme ☉ Cleveland, Medical Department of Ohio Wesleyan University, Cleveland, 1905, on the staff of the Lutheran Hospital, aged 53, died, May 19, of gastric carcinoma and myocarditis

James Gilbert Howell, Enville, Tenn. (licensed in Tennessee in 1910), member of the Tennessee State Medical Association, aged 57, died, May 7, in a hospital at Jackson, of chronic arthritis and pneumonia

Lambert C. Brewer, Los Angeles, Atlanta College of Physicians and Surgeons, 1901, member of the California Medical Association, aged 59, died, May 10, in a local hospital, of pulmonary tuberculosis

David A. Williams, Nangua, Mo., Missouri Medical College, St. Louis, 1882, member of the Missouri State Medical Association, for many years bank president, aged 81, died, May 9, of pneumonia

John W. Howard, Oklahoma City, Kentucky School of Medicine, Louisville, 1876, member of the senate in the first territorial legislature, aged 87, died, May 10, of cardiorenal vascular disease

Lewis Carl Cook, Columbia, Miss., Memphis (Tenn.) Hospital Medical College, 1911, member of the Mississippi State Medical Association, aged 60, died, in May, of acute dilatation of the heart

Alfred McKinnon Curl, Quincy, Ohio, Jefferson Medical College of Philadelphia, 1891, member of the Ohio State Medical Association, served during the World War, aged 69, died, May 10

Joseph Browne Jackson, Zanesville, Ohio, Howard University College of Medicine, Washington, D. C., 1925, served during the World War, aged 40, died, May 13, of heart disease.

Robert Leeper Doig, San Diego, Calif., College of Physicians and Surgeons, Keokuk, Iowa, 1880, member of the California Medical Association, aged 81, died, May 9, of heart disease

Samuel John Will, Jefferson Barracks, Mo., Missouri Medical College, St. Louis, 1880, member of the Missouri State Medical Association, aged 77, died, May 18, of arteriosclerosis

Frank M. Solar ☉ Cincinnati, Medical College of Ohio, Cincinnati, 1890, on the staff of St. Francis Hospital, aged 67, died, May 22, of hemorrhage due to an intra-abdominal tumor

Henry George Meyer, Chicago, Hering Medical College, Chicago, 1906, member of the Illinois State Medical Society, aged 66, died, May 8, of cardiac decompensation and nephritis

John Driver, Ogden, Utah, Marion Sims College of Medicine, St. Louis, 1891, honorary president of the Utah State Medical Association, aged 87, died, May 8, of myocarditis

William Henry Flint, Perry, Mich., Detroit College of Medicine, 1897, formerly a minister, aged 77, died, May 4, in a hospital at Lansing, of carcinoma of the bladder

Lovick Thomas Pattillo, Atlanta, Ga., Atlanta College of Physicians and Surgeons, 1904, formerly state bacteriologist, aged 60, died, May 12, of carcinoma of the larynx.

Frank J. Livingston, Salt Lake, Pa., Eclectic Medical Institute, Cincinnati, 1888, bank president, formerly county coroner, aged 67, died, May 5, of cerebral hemorrhage

Tobe E. Dalton, Opp, Ala., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1894, aged 69, died suddenly, May 4, of heart disease

Calvin S. Branyon, Valdosta, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1892, aged 76, died, May 3, of myocarditis

Andrew B. Estock, Eugene, Ore., Dunham Medical College, Chicago, 1901, aged 65, died, May 19, following an operation on the prostate

Orland L. Cook ☉ Pittsburgh, University of Louisville (Ky.) Medical Department, 1911, aged 55, died, May 5, of cerebral hemorrhage

West B. Bailey, White Plains, Ky., Kentucky School of Medicine, Louisville, 1891, aged 75, died, May 8, of cardiovascular renal disease

James McKissick Moore, Spring Hill, Tenn., University of Nashville Medical Department, 1875, aged 87, died, April 18, of senility

Bert P. McWhinney, Indianapolis, Eclectic Medical Institute, Cincinnati, 1897, aged 67, died, April 14, of cardiovascular renal disease.

Michael J. Flanagan, Shamokin, Pa., Jefferson Medical College of Philadelphia, 1890, aged 68, died, May 16, of chronic myocarditis

Charles M. Steward, Kansas City, Mo., Eclectic Medical University, Kansas City, 1913, aged 58, died, April 23, of heart disease.

Peter Douglas McLean, Woodbridge, Ont., Canada, University of Toronto Faculty of Medicine, 1879, aged 79, died, April 5

Sylverter Summerfield Thomas, Maben, Miss., Louisville (Ky.) Medical College, 1889, aged 70, died, April 24, of pneumonia

Jessie Thomas Orr, Olathe, Kan., Woman's Medical College, Chicago, 1886, aged 72, died, May 4, of carcinoma of the liver

Benjamin F. Herring, House, N. M. (licensed in New Mexico in 1905), aged 77, died, May 5, of cerebral hemorrhage

James McDougale Humboldt III, Rush Medical College, Chicago, 1877, aged 83, died, May 13, of cerebral hemorrhage

C. P. Capps, Meherrin, Va., University College of Medicine, Richmond, 1895, aged 68, died, May 12, of cerebral hemorrhage

Alexander L. Davidson, Chicago, Chicago Medical School, 1922, aged 46, died, May 21, of coronary thrombosis

L. R. McClain, Cookeville, Tenn. (licensed in Tennessee in 1879), aged 91, died, in April, of senility

Bureau of Investigation

THE "GLYOXYLIDE" OF WILLIAM F KOCH

New Steps in the Evaluation of the Detroit Cancer Cure

On April 6, 1936, the Bureau of Investigation received from an Alabama physician what was to be the first of numerous inquiries regarding William F Koch and his "Glyoxylide." The inquirers had received an advertisement consisting of a one-page printed letter bearing the heading "Koch Laboratories" and carrying the names of William F Koch, Ph D, M D, and G J Warnshuis, M D

The body of the letter was devoted to what the signatory, Koch, was pleased to term "the most important recent achievement in medicine." The name of this "recent achievement" was "Glyoxylide." The promulgators claimed they had "demonstrated its efficiency not only in the treatment of cancer, but also in such infections as tuberculosis, psoriasis, leprosy, poliomyelitis and syphilis."

Koch sends with his letter a four-page leaflet. The leaflet contains several remarkable photographic reproductions of the "before and-after" type entitled "Examples of Efficiency of Natural General Immunity Body Synthetically Reproduced."

The first page of the leaflet depicts two photographs. One above the title "4 years of intense suffering with Psoriasis," shows a man covered with skin lesions. The other is entitled "Recovery after 2 Injections of Glyoxylide." No other explanation is offered. The time interval between injections is not mentioned, although in the recovery picture several inches have apparently been added to the patient's girth.

The second page of the leaflet contains under the caption "Cancer of Stomach," two photographs of "Mr R." The upper picture carries the legend "Mr R before treatment. Note the bulging of the cancer masses throughout the abdomen." A picture similar in all details of shadows and highlights appears on page 38 of the book "Natural Immunity" published by Koch. To this picture is appended the legend "Mr R after recovery. Abdomen completely normal. All traces of cancer masses have been absorbed." Below the picture of "Mr R." in the leaflet and in the book is another picture of "Mr R," with the legend "Mr R abdomen drawn in to show the freedom from cancer masses." A careful comparison of these four pictures shows identical folding of the patient's shirt. It is difficult to conceive of Mr R's clothing being folded in exactly the same way on different occasions. If the leaflet pictures are to be accepted, Glyoxylide evidently works so rapidly that the cancer masses melted away before Mr R had an opportunity to pull down his shirt.

Koch's presentation of the theoretical basis of his treatment involves a smattering of the sciences, thoroughly agitated in the authors' cerebrum and poured on paper. One reads of the reputed peregrinations of electrons in body processes, the alleged effects of mitogenetic and necrobiotic rays, oxidative processes unknown to biochemistry, an alleged relation of photochemical reactions to the effects of carcinogenic hydrocarbons, and immune reactions completely foreign to modern immunology. The phraseology may be impressive to the novice, to any one with even a modicum of scientific education the major portion of the treatise is pure nonsense.

The author presents what purports to be a chemical reaction whereby "Glyoxalic acid" passes by way of glyoxal into glycollic acid and oxalic [sic] acid with the unsaturated diketone, vinyl dioxide in hydrated form as an intermediary.

Careful inspection of the structural formulas alleged to represent these substances shows that only one of them (oxalic acid) is properly indicated. The exact nature of Glyoxylide is not stated; this compound presumably has something to do (just what is not clear) with an alleged unsaturated diketone which Koch represents thus

This appears to be as incomprehensible as the other structural formulas already mentioned, the existence of such a compound is at least improbable.

A companion piece of Koch's Glyoxylide letter emanating from the same Detroit address, is from Gerrit John Warnshuis,

announcing his identification with the Koch Cancer Clinic. In this Warnshuis states in the second paragraph

"After eighteen years of extensive clinical tests it is now clearly apparent that the vicious persistency of the American Medical Association in adhering to its original policy of accepting the hasty condemnation given by the Wayne County Medical Society to Koch's work is unjustified and against public interest. Those familiar with the facts are quite aware that the original report of the Wayne County Medical Society was not based on any serious scientific investigation of the subject. This situation has been quite clearly described in previously published statements by Dr Koch, copies of which can be had upon request."

The Koch nostrum has been for some eighteen years before the medical profession and there is nothing even slightly resembling scientific evidence to justify any confidence in its merit. In 1918 William F Koch of Detroit was graduated in medicine by the Detroit College of Medicine and Surgery. He had been an assistant in physiology and an instructor in histology in the University of Michigan Medical School. He also had been professor of physiology in the Detroit College of Medicine and Surgery. Less than a year after his graduation in medicine Dr Koch announced that he "had developed a real specific cure for cancer." His thesis at that time seemed to be that cancer was caused by a micro organism resembling the spirochete of syphilis. He claimed that he had developed a differential poison—"Koch's Synthetic Anti-toxin," that would destroy the cancer germ without injuring the host. This remedy has been described in one place as "a synthetic chemical compound of very definite molecular arrangement" and in another place as a "difficultly prepared synthetic structure, worked down on a recrystallization process"—two descriptions that make up in sonorosity what they lack in clarity.

Undisputable records do not reveal a single instance in which a case of unquestioned malignant disease has been cured by the Koch treatment. There is, however, plenty of information regarding individuals who "promptly died" after taking the treatment.

At different times the Wayne County (Detroit) Medical Society has appointed three committees to investigate Koch's "cure." Each of the three reports has been unfavorable.

These facts have been discussed at different times in THE JOURNAL, and the matter is available in reprint form to any one who will send a self-addressed, stamped envelop for it. The Koch treatment is a highly commercialized promotion of a nostrum now elaborated from limitation as a cancer cure to the fields of tuberculosis, psoriasis, asthma and similar chronic conditions. Cancer quackery is cruel and ghoulish. The other conditions are chronic diseases involving great numbers of people ever hopeful and therefore a fertile source of income for all varieties of charlatanism. The record of Koch during the eighteen years since he first appeared on the horizon of quackery is not such as to indicate any safety in reliance on him or his products. His new associates are not reputed for scientific attainment or for any other reason except the kind of repute earned by association with William F Koch.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States
Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Live On Treatment.—Live-On Medicine Co. St. Louis. Composition: Essentially rhubarb extract, tar, vinegar, alcohol and sirup. For coughs, catarrh, asthma, etc. Fraudulent therapeutic claims.—[N. J. 21227 August 1934]

Glenn's Sulphur Soap.—Century National Chemical Co. New York. Composition: Essentially sulfur (34 per cent) soap (59 per cent) per fume and water. For skin disorders such as eczema, acne, etc. Fraudulent therapeutic claims.—[N. J. 23799 May 1935]

Correspondence

STATUS OF ALLERGY TEACHING

To the Editor—In THE JOURNAL, April 18, page 1409, Dr Richard A Kern comments on my article entitled "Status of Allergy Teaching as Indicated in Medical School Announcements," which appeared in THE JOURNAL, Aug 31, 1935, pages 744-746.

A reply would require reprinting my entire article, the points that he raised are answered not only in the body of my article but also in tables analyzing the data.

I have a few extra reprints for any one interested in the controversy.

I HARRISON TUMPEER, M.D., Chicago

THE LEUKOPENIC INDEX AND FOOD ALLERGY

To the Editor—The editorial on "The Leukopenic Index and Food Allergy" in THE JOURNAL (June 6) refers to eight papers by various authors, on variations in the leukocyte count, either fasting or postprandial. These quotations emphasize the sometimes extremely wide variation in leukocyte counts even the fasting counts, when they are repeated at long or short time intervals.

While the quotations are correct, they do not consider the fact that these wide fluctuations take place almost always in the afternoon and that the morning white counts are surprisingly constant as compared with those of the afternoon.

With one exception the articles referred to show that it is customary to observe a fasting fluctuation of around 2000 during the morning hours although, as in my experience, there are exceptions. The one article in which this is not true deals only with infants under 25 weeks of age. It is well known that there is a very pronounced variation in white counts in the new-born.

The leukopenic index determination is made in the morning, with the patient fasting. My own observations on the normal morning fluctuation of the fasting white counts as based on leukopenic index studies are quite in agreement with the morning observations of the authors referred to. Their observations are not opposed to my own. A detailed analysis of the observations of these authors will appear in the September issue of the *Journal of Laboratory and Clinical Medicine* under the title "The Leukopenic Index as a Diagnostic Method in the Study of Food Allergy."

WARREN T VAUGHAN, M.D.,
Richmond, Va.

GLOMUS TUMORS

To the Editor—The article "Glomus Tumor" by F J Jirka and C S Scuderi in THE JOURNAL, July 18 gives a fairly complete bibliography but fails to mention two articles in the English literature. One is a complete description of this condition with expensive color photographs by Victor Raisman and Leo Mayer under the title of "Tumor of the Neuromyo-Arterial Glomus" and appeared in the *Archives of Surgery* (30 911-929 [June] 1935). THE JOURNAL of July 27 1935 gave quite a long abstract of this on page 313. The other is an article by M S Furman and A M Gold in the *New York State Journal of Medicine* (35 618-620 [June 15] 1935). In the bibliography of this second article there is reference to an article by F E Adair (Glomus Tumor *Am J Surg* 25 1 [July] 1934). These three papers deserve mention as they appeared before the excellent description by Lewis and Geschickter mentioned in the bibliography.

ABRAHAM S ROTHEBERG, M.D., New York.

EFFICACY OF GARGLES

To the Editor—In a communication to THE JOURNAL, May 9 page 1679, I mentioned my objection to the roentgenographic method of investigating the efficacy of the gargle, as well as the fallacy of the conclusions arrived at by this method. I mentioned that it was more logical to inspect the interior of the throat directly and stated that after gargling with a suspension of bismuth the mouth, pharynx, tonsils and piriform recess are found coated with the bismuth.

June 27 there appeared in THE JOURNAL, page 2253, a communication from Dr H M Walker of London, stating that he fully agreed with my conclusions. He mentioned, however, that on investigation of ten patients whom he had gargle with a solution of methylene blue after administration of atropine, in no instance had the fluid reached (stained?) the tonsil, posterior pharyngeal wall, or other structures. This led him to the conclusion that gargling was entirely useless as a method of introducing an antiseptic medication to the tonsil or pharynx. His experience being at such variance with my own, I find it necessary to continue the controversy or leave the impression of agreeing with Dr Walker's conclusions.

In my original investigation I also employed a gargle of methylene blue solution (2 per cent aqueous), and after gargling for a whole minute I was surprised on inspection that the vigorous agitation had left the mouth and throat of the patient unstained. I then tried application of the solution with a cotton swab and found it almost impossible to stain the normal mucous membrane of the mouth and throat. The tongue of course staining readily. I then tried a bismuth suspension, which, as I stated, coated the mouth, tonsils, posterior pharynx and piriform recess. This of course is no indication of the efficacy of the gargle but of the fact that the solution does reach these various parts of the mouth and throat.

JULIUS KAUNITZ, M.D., New York.

BARBITURATES AND IRRADIATION

To the Editor—In THE JOURNAL, May 2, page 1588, Dr I S Trostler of Chicago discussed briefly the harmful effects of the barbiturates during irradiation. A case reported by Uhlmann on roentgen reaction elicited by barbiturates (*Deutsche med Wochenschr* 63 216 [Feb 7] 1936) is incorporated in Trostler's note.

Our review of Uhlmann's original report suggests strongly that it was a case of ordinary dermatitis medicamentosa. It is generally accepted by dermatologists and radiologists that a drug eruption will cause the skin to be more sensitive to any type of external irradiation. Since the appearance of an eruption due to barbiturates is relatively rare in view of their extensive use, and since it usually develops in people with marked hypersensitivity, it seems that the use of barbiturates to overcome nausea and vomiting as a result of irradiation is not contraindicated. We have previously reported (Popp, W C Nausea and Vomiting Following Roentgenologic Treatment *Proc Staff Meet Mayo Clin* 11 222 [April 1] 1936 discussed by M W Binger, p 223) the beneficial effect of pentobarbital sodium in preventing roentgen nausea. We have used pentobarbital sodium in doses up to 4 grams (0.26 Gm.) at each treatment session and have in some cases given total doses of 30 grams (2 Gm.) in a series of more than 15 patients undergoing roentgen treatment. We have seen no excessive roentgen skin reactions in any case and since the drug produces definite relief of roentgen nausea we feel that its continued use is indicated in spite of the fact that it rarely cause a drug eruption.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TOBACCO AND HEART DISEASE

To the Editor—A few days ago I was called to a restaurant to examine a man aged 76 who had suffered a momentary syncope shortly after finishing a light supper. There was nothing to the supper or to the circumstances at the time that could be especially implicated as causing the ictus. On examination I found a blood pressure of 150 systolic, 100 diastolic and a pulse rate of 56 beats per minute with an occasional extrasystole. There were no abnormal sounds or murmurs on auscultation of the precordial area. I put the patient to bed ordering absolute repose. Finding that he was in the habit of smoking six cigars during the afternoon and evening I limited him to one after dinner and one after supper, believing that the psychologic effect of limiting the number would be preferable to the absolute prohibition of smoking after so many years of indulgence. The patient was quite worried as to the slight irregularity in his pulse for he said that he had had a physical check up shortly before coming to Mexico City and that no such irregularity had ever been encountered. For that reason I referred him to an eminent cardiac specialist in this city for examination. The electrocardiogram showed an interpolated ventricular extrasystole in lead 1 and slight negative irregularity ST in lead 2. The consultant diagnosed an arteriosclerosis and gave his opinion that the disturbance the week before was of coronary origin. He absolutely forbade the use of tobacco. (Blood examination the day after the attack showed urea nitrogen 17.35 mg per hundred cubic centimeters of blood; urinalysis a few pus cells. Subsequent blood pressure readings have been between 115 and 140 mm. of mercury maximum.) The reason for my letter is the advertisements that have appeared in *THE JOURNAL* of the Canava Cigars in the Nov. 2, 1935 issue and the advertisements of the Health Cigar Company appearing weekly. Does the publishing of these advertisements indicate that the Council on Pharmacy and Chemistry approves these products and the advertising copy? The article by Lampson in *THE JOURNAL* June 1, 1935, page 1963 is quite encouraging as to permitting the use of denicotinized tobacco but Wright and Moffat's article of Aug. 4, 1934, page 318 does not seem in complete accord and the previous article on the Nicotine Content of Tobacco (July 29, 1933, p. 385) shows quite a variable content in so-called denicotinized cigars and cigarettes. Just how liberal can one be in their use, and do you think that in the present case it would be permissible to allow a cigar after meals preferably of the type advertised in *THE JOURNAL*. M.D.

ANSWER.—The reasonable limitation of tobacco advised in this case is in accord with the opinion of a large number of physicians specializing in heart disease in this country. One cigar, preferably of a partially denicotinized type, after meals, should not cause harm even though there is a moderate amount of heart disease present, unless it is clear that this use of tobacco precipitates trouble. There are many individual variations, but most patients can use a moderate amount of tobacco without toxic symptoms and without harm to the heart.

It seems unlikely that in the case in question there is any severe acute coronary disease. The momentary syncope does not point to this in the absence of other symptoms, and extrasystoles certainly do not indicate its presence. The electrocardiogram did apparently show some abnormality of the ST interval in lead 2. Some chronic heart disease, most likely coronary disease, may have been responsible. On this finding alone one cannot diagnose coronary occlusion.

On general principles it is well in the presence of coronary disease to advise moderation in all things, including tobacco. The complete omission of tobacco is often worth while in such individuals if such omission does not cause great discontent, but it is not usually essential.

INCUBATION PERIOD

To the Editor—What is the derivation of the term incubation period? Can you refer me to comprehensive articles on incubation periods? What is the present-day explanation of the incubation period? Please omit name.

M.D. Massachusetts

ANSWER.—Incubation is derived from the Latin verb *incubare* to hatch out, and incubation in one sense means hatching. To find out just when and where incubation was introduced into medical literature would require a great deal of work. The Oxford Dictionary refers to its use by George Gregory in the fourth edition (1835) of his *Elements of the Theory and Practice of Physic*. In one of the earlier editions Gregory makes this statement: "Attempts have been made to ascertain the exact period at which contagion begins to exert

its influence, and it has been satisfactorily shown in this respect that each particular contagion acknowledges a different law." With time the conception of incubation became clearer and in Austin Flint's *Treatise of the Principles and Practice of Medicine*, 1886, page 97, one reads "Incubation, signifying hatching, relates to the time which elapses after the reception of special causes of disease before any morbid manifestations take place. For example, after inoculation with the virus of smallpox a certain number of days elapse before any morbid phenomena make their appearance. But, in the meantime, occult operations are going on in the system, and when these are sufficiently advanced the period of invasion or access begins. The significance of the word incubation is thus apparent. It is rendered especially significant by the germ doctrine of the causation of many diseases. The existence of the period of incubation is one of the points in evidence of the truth of this doctrine." At present the incubation period is generally interpreted in harmony with this statement as the time that elapses between the entrance into the body of the agent of an infectious disease and the clinical manifestations of that disease. What happens during this period? In diseases such as diphtheria and scarlet fever, in which the main disturbances are not due to generalized infection but to intoxication by specific toxins, the incubation period would seem to be occupied with the elaboration in the throat and other places of local infection of sufficient toxin to cause characteristic symptoms. The time required appears to vary somewhat from case to case, hence the incubation period of diphtheria and of scarlet fever, though comparatively short, varies in length. In certain other diseases, notably measles, smallpox, chickenpox and vaccinia, the incubation period is longer and as a rule more precise. Here there is reason to believe that during incubation the infectious agent, which may be multiplying sets up reactive processes in the body of the patient with elaboration of specific antibodies, and that the acute attack is caused by the products of the interaction between the infectious agent, the antigen, and the specific antibodies. Undoubtedly the two lines of explanation now suggested of the incubation period may play a varying part in different infections. At any rate the specific poisons of infecting microbes and the reaction between microbe and specific antibodies both take part in the phenomena of infection and both require time for their evolution.

VASOMOTOR RHINITIS

To the Editor—In a definite case of vasomotor rhinitis in which no etiologic factor can be found after thorough skin testing by a most competent allergist and the nasal secretions show an eosinophil count of 25 per cent, what can be done to offer relief? The patient has no intranasal disorder and does not respond to the nasal treatment of ephedrine, epinephrine and so on. Ionization has been tried three times (eight minutes 10 milliamperes on both sides) with only temporary relief. There is no allergy or history of allergy in the family. How can one prove to one's satisfaction a physical allergy and if so what can be done? I would appreciate any suggestion as to treatment. What do you think of alcohol injections intranasally? Please do not use my name.

M.D. New York.

ANSWER.—The presence of an eosinophil count of 25 per cent in the nasal smear would seem to clinch the diagnosis of "allergic rhinitis, despite the failure of the history and skin tests as clues to finding the cause of symptoms. Let it be assumed that skin tests have been adequately carried out, with tests for all possible causative factors including foods, animal derivatives, pollens and such miscellaneous substances as orris root, cottonseed, house dust, flaxseed, silk and pyrethrum.

In many cases of vasomotor rhinitis the skin tests will be negative yet the symptoms can be shown to be due to hypersensitivity to one or more substances. It is necessary then to try various clinical procedures. First of all the usual causes of vasomotor rhinitis should be avoided as completely as possible—contact with animals, as the dog, cat or horse. Feather pillows or comforters should be removed, in many cases excellent results are obtained by enclosing completely the pillows and mattress in rubberized sheeting, sewed securely. Orris root is probably the most common cause of vasomotor rhinitis in women, there are several orris root-free cosmetics on the market, any one of which may be recommended. Ozite paddings under carpets should be removed if present, as well as dusty rugs, curtains or drapes. Occasionally the symptoms come from some ordinary drugs, such as quinine or acetylsalicylic acid. Sometimes occupational dusts may be factors, such as wheat flour, cottonseed linseed or flowers. Foods too are frequent offenders and elimination diets may be very successful. There are various ways of trying these, such as (1) beginning with milk alone for two or three days and then adding foods, (2) starting with a full diet and gradually removing suspected foods, or (3) starting with simple fixed diets and adding new foods at intervals. Food diaries are helpful.

If all these measures fail, one must turn to nonspecific measures, of which there are many. Vaccine therapy, autogenous or stock (no special choice), is probably the best. Injections of iodides sometimes are of service. Autohemotherapy occasionally is an aid. As ionization has failed it is unlikely that any other local procedure will succeed, though injections of alcohol may be tried, that method is not recommended.

It is well in all cases to build up the general resistance of the patient to as high a standard as possible. To this end removal of foci of infection, tonics, glandular products when indicated and vitamin therapy are to be tried.

It is not easy to demonstrate physical allergy, although history of symptoms occurring only in cold air or in warm places, or only with exertion, are suggestive. Desensitization to heat and cold have been attempted by gradual exposure and some results have been reported.

PAIN IN OVARIAN AREA

To the Editor—I have under my care a woman aged 35, divorced, engaged in office work, who contracted syphilis several years before she became a patient of mine, and her symptoms were such that the disease was discovered only through the routine Wassermann test. In spite of intensive treatment we have been able to get only a negative Wassermann reaction. Since the disease had gone so long without any special treatment, however, I have not been greatly surprised at this. Two years ago I operated on her removing a chronically inflamed appendix and a cystic portion of the right ovary. I think now that probably much of the previous pain was caused by the ovary instead of the appendix. The most troublesome symptom now is a severe aching cramping pain in the lower right quadrant of the abdomen coming always between the fifteenth and the twentieth day after the beginning of the menstrual period. At times this is very severe almost disabling her for her work. The pain lasts usually for about three days and gradually disappears and an occasional attack is very mild. It is my own opinion that this pain is probably due to ovulation. On this basis I have wondered if it might be possible to sterilize the right ovary alone using the x-rays and if so whether or not it would probably bring about a cessation of the trouble. Any suggestions you may care to make with regard to this case will be gratefully received.

M D Nebraska

ANSWER—The relationship of the pain to ovulation can be determined less accurately from the time of the preceding menstruation than from that which follows ovulation. If the distress is acute and at its height approximately fourteen days prior to menstruation, it is very likely that the precipitating cause of the pain is ovulation. Even so, there is probably an associated pathologic condition.

In most cases with a history such as this, there are complicating pathologic conditions in the right lower quadrant, most often adhesions, sometimes an unhealthy ovary—perhaps adherent or cystic or both.

The use of x-rays for the purpose of producing ovarian atrophy is contraindicated in most patients with pain, because pain usually betokens an inflammatory condition or adhesions. Unilateral irradiation to produce atrophy of one ovary is rarely attempted and is not on record in a sufficient number of such cases to warrant deductions as to its efficacy. Theoretically the outlook is dubious with such treatment. Palliative care or surgical intervention preferably the latter would be the procedure of choice despite the fact that the patient has already been subjected to one operation.

SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

To the Editor—A man aged 30 had an intra urethral chancre with a 4+ Wassermann reaction two years ago. He was given about sixty 0.45 Gm doses of nearsphenamine about seventy five intramuscular injections of bismuth salicylate and about thirty of bismuth arsenamine sulfonate in continuous treatment. He still has a 3+ Wassermann reaction after two years of treatment. The patient has also had a chronic bilateral otitis media for about twenty years. What further treatment do you suggest? Would you recommend a spinal puncture in a patient with chronic otitis media?

HERMAN I. SWITZER, M.D. Bronx, N. Y.

ANSWER—It is essential that the patient's spinal fluid be examined to determine whether or not invasion of the central nervous system has occurred. The presence of a chronic otitis media is not a contraindication to doing a spinal puncture. If a positive spinal fluid report is obtained it is advisable that the character of the condition found be noted. For example, the test should include not only a Wassermann test but also a cell count (done soon after withdrawal of the fluid), a globulin estimation and a colloidal gold test. The degree of positivity or in other words the character of the spinal fluid report is a valuable guide in subsequent treatment. If the report shows evidence of a parietal formula fever therapy, (malaria) would seem warranted in this case. If a patient

has had intensive treatment, and a persistently positive spinal fluid is found, the use of nonspecific measures is warranted. If the patient's spinal fluid is weakly positive, persistence in treatment or the use of intraspinal therapy may reverse it to negative. If the spinal fluid report is negative examination of the heart and viscera for evidence of syphilis is advisable, and if such examinations are negative, the alternate use of courses of bismuth compounds and mercury, fifteen injections of each to a course at intervals of two months, are recommended. This treatment should be continued for the ensuing three years.

CHRONIC ARTHRITIS

To the Editor—A man aged 62, 6 feet (183 cm) tall, weighing 155 pounds (70 Kg) has lost 20 pounds (9 Kg) in five months but is in good general health. While playing tennis last July he noticed pain of a gnawing character in the right shoulder joint with sharp stabbing pain in the arm muscles and with stiffness and wasting of the muscles. The pain was relieved by exercise but soon returned. He feels toxic and fatigued but has no fever. The pulse is about normal. The pain gradually spread to the left shoulder and arm with pain and stiffness of the wrist joints and fingers and also involvement of the cervical and dorsal spine. Later it spread to the hip joints with aching and pain in the legs and feet. The pain is worst at night and he is unable to sleep more than an hour at a time. The urine is normal but he micturates excessively at night. The tonsils, teeth and sinuses have been explored by x-rays and found normal. There is no evidence of appendicitis or gall bladder infection. The prostate is quite large but without sign of any infection. There is a history of constipation during adolescence but not of late years. The stools are now greenish and pasty and he has to use laxatives and enemas for relief. His appetite is good but he feels drowsy, has a slight headache and is tired. The blood pressure is 130 systolic, 70 diastolic. The blood sugar is 170 mg. Blood count is normal except for a leukocytosis of from 13,000 to 15,000. The Wassermann reaction is negative. My diagnosis is atrophic arthritis and I first saturated him with salicylates without avail. Acetylsalicylic acid in doses of from 15 to 20 grains (1 to 1.3 Gm.), however, give him some relief. I have tried colloidal sulfur 10 grains (0.65 Gm) intravenously every other day but this has not given any relief. I have restricted carbohydrates in the diet and increased fruits and vegetables. Do you think my diagnosis is correct? What preparation of colloidal sulfur has met with most success and in how large doses? Are stock vaccines of any service? How about Russian baths or treatment at a hot spring? I will appreciate any suggestions for treatment in this case. Please omit name.

M D Chicago.

ANSWER—The presence of chronic polyarticular involvement with considerable disability, loss of weight and fatigue suggest chronic atrophic (infectious, rheumatoid) arthritis, although the patient is at an age when chronic hypertrophic arthritis is more common. A diagnosis of "tennis arm" is of course untenable in view of the polyarticular progression but the initial appearance and occurrence of symptoms in a region of trauma illustrate the importance of trauma in precipitation and progression of the disease and illustrate also the importance of reducing chronic trauma of weight bearing or occupation to the affected joints.

Careful attention to all foci seems to have been given. Special roentgenographic examination of the bowels, culture of the stool and tests of the passage of charcoal reveal data of questionable significance, therefore they cannot be urged, although they might be made. Sulfur in various forms is an old remedy for atrophic arthritis and has been discarded from time to time only to be revived periodically when a new preparation of sulfur is exploited. The use of colloidal sulfur is now being energetically pushed by various manufacturers. Only a few clinical reports are so far available. Some users are enthusiastic at times violently so, others have been disappointed with results. None of the work to date has been well controlled. Opinions differ as to the value of a low carbohydrate diet or of stock vaccines. If the patient does not improve materially after being on a restricted carbohydrate diet for a reasonable time it would be well to advise a fairly high carbohydrate, high vitamin, anticonstipation diet but to avoid obesity. If the arthritis is progressive a trial of stock vaccine is justified. The vaccines in most current favor are those of Dr. R. L. Cecil of New York, Dr. E. C. Rosenow of Rochester, Minn., and Dr. J. C. Small of Philadelphia and can be obtained by writing to these men.

Physical therapy or various sorts may provide more relief than any other treatment but should be used in conjunction with other treatment. The superior physical therapeutic facilities of spas are undoubted but if physical therapy is not continued consistently by the patient after leaving the spa the advantages of a short stay at a hot spring may be but temporary. The patient should be instructed in methods to be used daily in his own home and supplemented by professional physical therapy in a physician's office or physical therapy technician's office two or three times a week if possible. Instruction in

home physical therapy can be given by a trained technician or can be obtained by writing to Mr H A Carter, secretary of the Council on Physical Therapy of the American Medical Association

If an intensive program of adequate rest, daily physical therapy, a nutritious eliminative diet and trial of an arthrotropic streptococcus vaccine are not soon productive of improvement, attention to other available methods of treatment is in order and the correspondent is referred to a recent "Rheumatism Review" published for the American Committee for the Control of Rheumatism, which appears in the *Annals of Internal Medicine* for April, May and June 1935

MODERN TREATMENT OF VAGINITIS

To the Editor—Since August 1935 I have been treating a gonorrheal vaginitis and Bartholin abscess in a girl aged 6 years. She is in good condition except for this infection which is of about two years duration. Smears have revealed numerous gram negative intracellular diplococci on several occasions. Treatment began with a course of oral amniotin in doses of 1 000 international units three times a week. After ten weeks the patient showed a tinge of blood in smears and in the discharge. Smears at this time showed a mixed type of infection and the discharge was unabated. Treatment was changed to the Corbus Ferry gonococcus toxin which was given at weekly intervals until a maximum dosage of 0.4 cc. of the undiluted toxin was given. This resulted in the healing of the Bartholin abscess which had continued to discharge following electrocoagulation and incision. At this point the treatment with oral amniotin in doses of 1 000 international units three times a week was resumed. At the end of the second week the discharge showed a slight bloody tinge. The discharge is profuse and there are numerous organisms diplococci and bacillary in form. The vaginal discharge is profuse. What is the proper dose of oral amniotin for a child of this age? Have you any suggestions as to treatment? All local remedies such as irrigations suppositories, ointments and local applications have been of no avail. Is non specific protein therapy advised? Please omit name. M D Nebraska

ANSWER—The treatment with preparations containing estrogenic substance is purely empirical and the dosage is unsettled. The treatment is intended to stimulate proliferation of epithelial cells of the vaginal mucous membrane and thus render the vagina more resistant to infection. R M Lewis (*Am J Obst & Gynec* 26 593 [Oct.] 1933) advised small doses of theelin given at short intervals in the belief that they are more effective than larger doses given less frequently. The hormone treatment has not, however, been generally accepted as a cure of gonorrheal cervicovaginitis. The gonococcus attacks glandular structures such as are found in the endocervix, Skene's and Bartholin's glands, and recurrence or persistence of the discharge is usually due to latent infection in one of these sites.

Te Linde and Bawner (*Am J Obst & Gynec* 30 512 [Oct.] 1935) report that the oral use of amniotin was ineffective in their cases of gonorrheal vaginitis in children but that the daily hypodermic administration of amniotin in oil gave good results and the daily use (at bedtime) of amniotin vaginal suppositories produced excellent results. Presumably, other estrogenic preparations would be equally effective.

In chronic cases of cervicovaginitis such as the one described, a vaginoscopic examination should be made. By this means the source of the discharge may be disclosed. A male urethro-scope may be used as a vaginoscope and the examination can be made without anesthesia. If the cervix is observed to be infected, electrothermic cautery treatment may be given as in adults with chronic endocervicitis (Titus, E. W., and Notes, *B Arch Pediat* 50 284 [April] 1933). Topical applications of weak solutions of silver nitrate may be made to the infected areas by direct vision through the vaginoscope. These may be followed by daily instillation of 1 per cent mercurochrome ointment (Stein, I. F., Leventhal, M. L., and Sered, Harry. *Cervicovaginitis, Am J Dis Child* 37 1203 [June] 1929) or by irrigation with 1 per cent lactic acid solution.

L. H. Biskand (*Surg Gynec & Obst* 57 261 [Aug.] 1933. *Lancet* 2 1049 [Nov 9] 1935) and José Farriols (*Arch de med, cir y especialid* 38 52 [Jan 30] 1935) report excellent results in the treatment of vaginitis by the use of basic phenylmercuric nitrate or phenylmercuric borate, which have the highest antiseptic potency of any compounds so far discovered. (Report of the Council on Pharmacy and Chemistry, *THE JOURNAL*, April 14, 1934, p 1224). The technic as given by Biskand for treating vaginitis in children is as follows. An endoscope is inserted when possible, a smear taken and 1 or 2 cc. of a 1:1,500 aqueous solution of basic phenylmercuric nitrate is instilled with a blunt syringe into the vagina, the hips are elevated and the solution is thus retained for several minutes. This is done once or twice a week. Daily or twice daily irrigations are made with a pint of 1:25,000 solution of basic phenylmercuric nitrate by means of an infant enema tip or a soft rubber catheter.

DYNAMICS OF HEART AND CIRCULATION

To the Editor—A man aged 70 who has had attacks of paroxysmal tachycardia at irregular intervals since the age of 15 was seized with an attack at 2 30 p. m. February 2 which lasted until 5 40 p. m. the same day. His pulse rate in the attack was found to be 210 which is three times his ordinary pulse rate. His blood pressure which is ordinarily about 130 systolic and 80 diastolic, was found to be 76 systolic and 60 diastolic. There were no signs of congestive circulatory failure no rales over the pulmonary bases no coldness of the extremities or visible edema. The blood pressure remained about the same as already noted (76/60) for half an hour after the cessation of the attack and then began to rise. These observations were made by another physician who reported them to me. The query suggested by these observations is this: Does the commonly accepted theory of the dynamics of the circulation which is expressed in a recent textbook on physiology (Wiggers. *Physiology in Health and Disease*, 1934 p 509) as follows: The ventricles pump the blood from the terminal reservoirs (auricles) into the distributing system under an initial pressure sufficient to secure a continuous capillary flow as well as a return flow to the heart fully explain the circulatory dynamics in this case? Could the heart alone contracting at the rate of 210 per minute in the very low portion of the blood pressure scale (76/60) and with a pulse pressure of only 16 develop force enough to push the blood mass through the vascular circuit in the accepted circulation time against the resistance in the hundred thousand miles or more of vascular tubing (Statistical Data in Human Anatomy *THE JOURNAL*, May 12 1934 p 1632) in the successful manner in which it was observed to be done in this case?

EDWARD E. CORNWALL M D, Brooklyn

ANSWER—No difficulty is offered in explaining the facts presented in accordance with the currently accepted views concerning the dynamics of the heart and the circulation. When the heart rate increases to 200 or above a minute, the period of diastolic filling is cut short to such an extent that not only each systolic discharge but also the minute output is decreased. The effects on systolic and diastolic blood pressure are those of decreased systolic discharge, i. e., the effects would be the exact opposite of those described in the textbook mentioned, page 600, for augmented systolic discharge. No other dynamic effect is conceivable than that systolic pressure should fall more than diastolic. This is beautifully illustrated by the data in the case presented.

It must not be forgotten that the blood pressure 76/60 mm. of mercury in the central vessels, regardless of how created, represents the pressure head that forces blood through the vascular circuit. References to the hundred thousand miles of vascular tubing should not be misinterpreted. It is conceivable that the minute vessels, if placed end to end, might stretch round the globe just as considerable linear mileage could be calculated if all the streets of Brooklyn were similarly connected. It would be unfair, however, to leave the impression that a tourist passing through Brooklyn would actually have to travel that distance or would meet the traffic resistance of all the streets combined. This is equally true for circulating corpuscles.

SPECIFIC GRAVITY OF URINE

To the Editor—Assuming that the temperature of the water is the same as the urine and that no protein is precipitated is the specific gravity of urine diluted with water in direct proportion to the dilution? I have apparently not found this to be the case although I admit that I have not controlled the temperature. Thus a specimen of 15 cc was diluted with 30 cc. of water and the specific gravity was 1.012 was the true specific gravity 1.036? Another was diluted with equal parts of water and the specific gravity was 1.018 was the true specific gravity 1.036?

SAMUEL L. IMMERMAN M D Philadelphia

ANSWER—At a constant temperature and in the absence of any precipitation, the specific gravity of the urine diluted with distilled water will vary in direct proportion to the dilution. A specimen with a specific gravity of 1.036 diluted with an equal amount of water should show 1.018.

Specific gravity is one of the most important tests in estimating renal function. The procedure is simple but before placing reliance in the results one should be certain that the readings are correct. The urinometer should be twirled as it goes into the urine to prevent adhesion to the side of the container and also to remove any air bubbles that might adhere to the bulb. The urinometer should be a long one with a stem at least 3 inches long, and should be graduated from 1.000 to 1.040. The very small urinometers with close graduations are worse than useless.

Each urinometer should be tested by immersion in distilled water at room temperature, when the reading should be exactly 1.000. It should again be tested with an accurate 5 per cent solution of sodium chloride, which will give a specific gravity of 1.035 at 25 C (77 F).

The specific gravity of urine varies considerably with the temperature. At body temperature of 37 C. it is 5 points lower than at 25 C., or room temperature. For urines at extreme

temperatures, corrections should be made by adding 0.001 for each 3 degrees centigrade above the temperature for which the urinometer is standardized, or subtracting 0.001 for each 3 degrees centigrade below. Some urinometers are supplied with a thermometer specially graduated for making quick corrections. It is always better to get sufficient urine than to dilute with tap water to make the reading.

USE OF DIGITALIS AS PREVENTIVE OF CARDIAC HYPERTROPHY

To the Editor—Christian asserts that digitalis apart from its value in controlling cardiac decompensation is valuable in inhibiting cardiac hypertrophy and retarding the aging process of the myocardium. Therefore he advises use of digitalis in all cases of hypertrophy and in cases in which hypertrophy is likely to appear (hypertension, murmurs, rheumatic heart disease with murmurs, and so on) for the remainder of the patient's life. He believes that cardiac hypertrophy instead of being a beneficent process has an injurious influence on the functions of the heart. I remember reading an article in which Cloetta proved Christian's contentions by animal experimentation. I have been considering advocating this therapy to a number of my patients but I should first like to know whether there is any evidence to show that such a long continued use of digitalis would be harmful and also whether larger doses of digitalis would prove successful in a patient with decompensations who had been taking digitalis for several years according to Christian's teachings. What seems to be the consensus among cardiologists concerning this form of preventive medicine? Is there much clinical proof to back it up? Please omit name.

MD New Jersey

ANSWER—As mentioned in the query, Cloetta has asserted that cardiac dilatation and hypertrophy secondary to experimentally induced aortic insufficiency of animals can be prevented or be reduced in degree by administering digitalis. Observations in man indicate that part of the beneficial effect of digitalis in patients with dilated and failing hearts is due to the increase in the "tonus" of the myocardium and to the reduction in the size of the heart. Evidence also exists showing that in the majority of instances cardiac hypertrophy is preceded by cardiac dilatation. Indeed, it is claimed that primary dilatation of the ventricles and the resulting stretching of the myocardial fibers serve as a stimulus to hypertrophy. Clinical observations indicate that a hypertrophied myocardium often is inadequate in function. Thus there is indirect support for the belief that digitalis may be beneficial in the prevention of ventricular dilatation and hypertrophy. Whether digitalis actually accomplishes such a function is not known, as the proof of such therapeutic action is exceedingly difficult to establish. Hence, such a therapeutic practice is based on clinical suggestion and on indirect evidence rather than on proof or on empirical results.

There is no reason to believe that the long-continued use of digitalis is harmful, or that it builds up "tolerance." Hence larger doses of digitalis will be beneficial in the presence of circulatory failure even if the patient has taken digitalis for several years previous to the onset of congestive failure.

Nevertheless it is fair to state that the practice of giving digitalis to patients with organic heart lesions but with no evidence of pulmonary or peripheral congestive failure is not at present an accepted procedure.

MISCARRIAGE WITH NOSEBLEED

To the Editor—A patient has had two pregnancies both terminating in miscarriage at the second and the sixth month. Each time the miscarriage was preceded by a persistent slight nosebleed. The nose felt congested and there was a slight steady ooze of blood. During the first pregnancy the nosebleed lasted for but a week. During the second it started two months before the patient went into premature labor. In each case the bleeding stopped immediately after the uterus emptied itself. Examination of the nares a few weeks later showed nothing abnormal. I did not see her during the pregnancies and do not know what condition her nose presented at that time. She tells me that she has had a few nosebleeds concomitant with menstruation and she does not recall any at other times. Do you think that there is any relation between the bleeding and the miscarriages? Can you suggest any procedure to insure her a successful pregnancy?

E. M. ABRAHAM, M.D. Brooklyn

ANSWER—It is difficult to explain the relationship of the nosebleed and the miscarriages in this case without more information. It would be essential to know the blood pressure and the results of urinary and blood examination. The state of the fetus and the placenta would also be enlightening.

There are a number of possibilities that might explain both the nosebleed and the miscarriages. There may have been some nephritis or toxemia with high blood pressure which could cause nosebleed and fetal death with abortion. There may have been some blood dyscrasia which would cause bleeding from mucous surface, such as the nasal and the uterine mucosa, and

which could account for both the nosebleed and the abortion. One should consider the possibility of syphilis, which might produce a nasal lesion with resultant bleeding and also cause a miscarriage. An infection of the upper respiratory tract might be responsible for one or both of the phenomena. Infectious organisms from such a focus might locate in the genitalia and cause fetal death. One should also exclude a malarial infection if the patient has lived in a district where such disease is prevalent. Malta fever might be considered, and the blood test for *Brucella abortus* should be carried out. In these days one has at least to consider endocrine factors. It might be worth while to determine the basal metabolic rate.

So far as treatment is concerned, one would have to be guided by additional information, but in general one would be justified in placing the patient on a diet rich in vitamins and minerals, making sure of a rather high calcium content with some iodine. Iron might be requisite if the woman should be anemic. With a low basal metabolic rate the administration of thyroid extract would, of course, be desirable.

This reply has been rather general, in view of the lack of greater detail in the query. It may be that close and detailed examination of the patient will fail to reveal the cause of the phenomena, the occurrence of which may be purely coincidental.

SUBCUTANEOUS EMPHYSEMA AFTER WOUNDS

To the Editor—A young Negro a hospital employee cut his finger on a clean metal door. The injury appeared trifling and the only treatment was application of an antiseptic (tincture of mercuriolate I believe). Within twenty-four hours a mild swelling and lymphangitis of the hand developed. He suffered no pain and his general condition was excellent. Within another twelve hours there was definite subcutaneous emphysema and the patient was hospitalized. Needling of the area (the dorsum of the hand and lower forearm) revealed gas and the swelling disappeared to recur within six or seven hours. His general condition gave no evidence of infection. The subcutaneous emphysema gradually subsided within three or four days and a complete recovery was made. Please discuss causes of subcutaneous emphysema especially as in this case in which I feel sure gas gangrene has been ruled out. Please omit name.

MD, Ohio.

ANSWER—Under the unusual causes of gas in the tissues one should consider inclusion of air beneath a blood clot or sutured wound such as of the abdominal wall and in injuries around compressed air machines. It is not likely that it would occur from an ordinary injury.

It is not uncommon to see air in the tissues in a roentgenogram for possible fracture after a rather extensive wound.

Gas may be produced in the tissues by *Bacillus Welchii* (*Clostridium Welchii*) types 1, 2, 3 and 4, *Vibrio septique* (*Clostridium oedematis-maligni* Koch), *Bacillus oedematis* (*Clostridium oedematis*), *Bacillus fallax* (*Clostridium fallax*), *Bacillus tertius* (*Clostridium tertium*) and *Bacillus coli* verus and *Bacillus coli-communior* (*Escherichia coli* and *Escherichia communior*).

The first five are strictly anaerobic and the colon group may grow under anaerobic conditions.

It is well known that *Bacillus Welchii* was the most common cause of gas gangrene (75 per cent) and wound emphysema following war wounds, although it was nearly always associated with other organisms, especially *Bacillus sporogenes* and *Bacillus histolyticus*, which are proteolytic but do not produce gas.

Of considerable importance is the fact that only certain very virulent strains of *Bacillus Welchii* can produce gas gangrene when present alone in a wound and then only when necrotized tissue is present. It is this requirement which led to the development and success of the surgical procedure of debridement.

In the first few days, smears from wounds with gas gangrene having a foul smelling reddish brown discharge usually show *Bacillus Welchii* and streptococci. In the second week the pus becomes more purulent and *Bacillus Welchii* is infrequent while streptococci, staphylococci and coliform bacilli are abundant.

The majority of war wounds having *Bacillus Welchii* infection cleared up without spreading gangrene. Dilute solution of sodium hypochlorite is of great value in the treatment of all gas-producing infections.

It is probable that the emphysema here was due to an avirulent or pure *Bacillus Welchii* infection. Certainly with careful cultures made on special mediums one could rule out infection by some other organism mentioned.

Treatment should demand the entrance of oxygen to the tissues either by wide opening of the wound or by surgical incisions. When muscle is infected extension is along the fibers necessitating incisions along the entire length of the muscle. If gangrene is present the entire muscle should be debrided and not infrequently amputation may be necessary.

DIFFERENTIAL DIAGNOSIS OF DERMATITIS

To the Editor—A woman, aged 68, developed an eruption on both hands about Oct. 20 1935. There was a previous similar attack a year before which was treated with hypodermic injections in the arm. An attack of herpes zoster occurred shortly after treatment was begun. Following the herpes the eruption on the hands disappeared. There is a history of anxiety and worry which preceded each eruption on the hands. The eruption began as ill defined patches of red fissured scaling skin between the third and fourth and the fourth and fifth digits of the left hand. An eruption then occurred on the flexor surface of the left wrist as a shiny reddish purple patch measuring 4 by 3 cm. It was flat and slightly infiltrated and the skin was thin and cracked. There was no exudation. A patch about 2 cm in diameter then appeared on the flexor surface of the right forearm at the junction of the middle and lower thirds. The dorsum of the right hand was next affected with an indefinite area of redness, scaling and fissuring which was not as severe as the preceding. The eruption is preceded by itching of mild degree and the itching continues after the eruption has occurred. In the small patch on the right forearm several pin point sized vesicles were noted. The skin of both hands and forearms is dry shiny wrinkled and thin at the elbows the skin abruptly changes to a normal appearance. Treatment with ultraviolet rays and 10 per cent naftalan ointment gave prompt relief in a week with return of the skin to normal appearance. Dressings with zinc oxide ointment were used later. When the dressings were removed to enable her to cook Thanksgiving dinner itching began in a few hours followed next day by the typical chapped fissured appearance of the eruption in the same locations as before. The patient has been instructed to avoid the use of soap and water on the hands and to wear rubber gloves while washing dishes but she has not cooperated very well. She was formerly using Palmolive and Woodbury's soap on the hands. She uses Espey's lotion on them at present.

M D Illinois

ANSWER—The eruption described may be a mild dermatitis venenata, an eczema or an eczematoid ringworm. The history of its having cleared after an attack of herpes zoster, and again on treatment with ultraviolet rays and 10 per cent naftalan ointment favors the diagnosis of a dermatitis due to irritation of an atrophic skin. Nevertheless scales should be examined for ringworm. Mental conditions, anxiety and worry may easily have something to do with bringing on an attack. Perhaps worries about her cooking, as at Thanksgiving or the heat or the irritation of soap and water caused a recurrence then.

The soaps mentioned are mild but no soap at all is still less irritating. Espey's lotion probably contains Irish moss, glycerin and boric acid. The patient should be patch tested for these ingredients, as well as for soap and any other substance she handles frequently.

Judging by the evident atrophy of the skin of the hands and forearms and the frequency with which dryness and sensitization to alkalis cause dermatitis during the fall, it is probable that the dermatitis is caused in this way and should be treated, as it evidently is already being treated, by the use of soothing and softening ointments and lotions, and abstinence from soap. Cooperation on the part of the patient is absolutely necessary to success or even partial success.

PSORIASIS

To the Editor—The special article on the treatment of psoriasis from the Cook County Hospital (THE JOURNAL July 13 1935 p 115) contains no mention of dioxyanthranol (anthralin). I have seen references in literature to dioxyanthranol as the modern substitute for chrysarobin. I am wondering whether dioxyanthranol is actually superior to chrysarobin and whether it seems that it will ultimately replace chrysarobin in the treatment of psoriasis. Information in regard to this will be appreciated. Please omit name.

M D Georgia

ANSWER—In the article mentioned as was stated, chrysarobin served only as the prototype of the general group of reducing substances to which it belongs. As other members in this group one may mention neorobin and dioxyanthranol. These were not mentioned, not because they are not of service but to keep the article within reasonable limits.

The exact merits of dioxyanthranol in comparison with chrysarobin cannot be definitely stated at present. Chrysarobin has had a much wider and longer use. It has stood the test of time. It is much cheaper than dioxyanthranol and does not deteriorate so rapidly. This is an important consideration when the combated eruption is widespread and large quantities of medicament are necessary. While chrysarobin may produce certain untoward reactions these are well known and can be avoided with reasonable care. Nor is the use of dioxyanthranol free of all danger. It may produce irritation, sometimes severe. It stains clothing to a lesser extent than chrysarobin and has less tendency to produce conjunctivitis. It has equivalent action in approximately one twentieth the concentration of chrysarobin. As a substance, dioxyanthranol is a much more intense reducing substance than chrysarobin and this intensity has been

measured. These data are to be published in the *Archives of Dermatology and Syphilology*. Dioxyanthranol samples from various batches is more uniform in strength, chrysarobin varies markedly in strength from sample to sample. Many dermatologists feel that the modern treatment of psoriasis with chrysarobin is more properly carried out in the hospital. With such proper use of chrysarobin, it is an efficient drug. It is too early since the more general use of dioxyanthranol in this country was begun to predict that it will entirely supplant chrysarobin, but the efficiency of the latter when properly used together with its easy availability makes this doubtful.

ENCEPHALOMYELITIS AFTER VACCINATION

To the Editor—A girl baby aged 13 months of normal full term delivery had an uneventful first few months of life except for the fact that she had obstinate constipation. She has been artificially fed for the past ten months. At 10 months of age the baby weighed 20 pounds (9 Kg). At this time she received an unsuccessful smallpox vaccination. This being negative a second vaccination was performed two weeks later. This resulted in a severe take and the child was ill for about ten days. In the meantime she had lost her appetite and became listless. The local and general reactions subsided but were followed by a marked generalized muscular flaccidity. Prior to inoculation she was beginning to crawl and sit up and she had made efforts to walk. Since the vaccination she has no longer made efforts to sit, crawl or walk. When an attempt is made to teach her to walk the legs crumple up under the effort. She cannot sit erect unless propped up. Her appetite has returned but constipation is still a marked symptom. She has developed a urinary incontinence and there is a dry desquamation on both legs. Her cry is weak by comparison to her previous cry. She is now 13 months of age and there has been no muscular improvement. Although she has gained a little there is still asthenia of a marked degree. Has this syndrome anything to do with the vaccination? Also what is to be done to improve the condition? These are the questions I should like answered.

M D, Chicago

ANSWER—In recent times in various parts of the world, notably in Holland and England, but in other countries as well not excluding the United States, cases of disseminated encephalomyelitis have been observed following vaccination. The first symptoms appear about the tenth day, though they may occur as early as the fourth or as late as the thirtieth day after vaccination. These patients complain of stupor, convulsions, headache, vomiting and fever. Ocular paralyses have been noted, with unequal pupils, but the involvement of other cranial nerves is not frequent. There is usually paralysis of the legs and loss of sphincter control. The neck is usually stiff, and Kernig's sign may be present.

Postvaccinal encephalomyelitis is less frequent in infants than in older children or adults. Many of these patients recover after a few weeks or months, though sometimes mental deterioration and spasticity may continue. It has been estimated that the mortality of postvaccinal encephalomyelitis is from 30 to 40 per cent. The designation of the disease, encephalomyelitis, indicates spinal cord involvement. A number of investigators have reported spinal cord lesions.

As has already been indicated, the majority of these infants tend to recover spontaneously, though unfortunately there are exceptions to this statement, because there may be residual effects. The baby may receive some benefit from warm baths, gentle massage, passive exercise and also a well balanced diet, with an eye to its nutritive qualities and the proper vitamin content.

MEASURING VISUAL CAPACITY

To the Editor—I am at a loss to interpret the degree of impaired vision of an applicant whose physical examination form (as submitted by a physician in California) shows Visual acuity R. 10/32 L. 10/32.1. Corrected R. 20/38.4 L. 20/38.4—A M A Rating. It will be appreciated if you can give your opinion of the percentage of visual acuity of this applicant with and without glasses.

R C O'Connor M.D. New York

ANSWER— $10/32.1 = 20/64.2$ (approximately 20/65)
 $= 47.5$ per cent visual acuity

$10/38.4 = 20/76.8$ (nearly 20/80)
 $= 42.5$ per cent visual acuity

NEW METHODS IN ACNE AND TRICHINOSIS

To the Editor—Would you be kind enough to give me some information regarding the treatment of acne vulgaris by means of manganese preparations and the value of silver arspenamine in the treatment of trichinosis?

A E. Dale M.D. Danville Ill

ANSWER—Neither of these forms of treatment could be considered as accepted or as scientifically established.

Permitted to come before the board for examination by reciprocity of the legislature.

Book Notices

Dental Roentgenology By LeRoy M. Ennis D.D.S. Assistant Professor of Roentgenology in the Thomas W. Evans Museum and Dental Institute School of Dentistry University of Pennsylvania Second edition Cloth Price \$6.50 Pp 351 with 093 Illustrations Philadelphia Lea & Febiger 1936

This book is not only one for the student but one that will be of great aid to the general practitioner. The introductory chapter with its statistics gives one quite a comprehensive knowledge, as well as keen insight regarding the value of dental roentgenology and the relationship that should exist between the dentist and the physician and vice versa. The early chapters give one a thorough understanding of the construction of the machine and the types of tubes, also a description of the electrical terminology, so that the reader knows just what is meant when certain terms are used. Dark room procedure which is important, is also discussed, as well as the care and precautions to be observed not alone by the operator but also toward his patient. The book also deals with another important phase of roentgenology, that of angulations and the various types of technic for the intra-oral and extra-oral as well as occlusal and bite-wing films, also for stereoroentgenography. What may be seen in one roentgenogram may not be seen in another angle of the same area. The greater part of the book, however, is devoted to dental pathology with a review of the normal anatomic landmarks of the teeth and jaws as seen in the roentgenogram. One does not realize that many of these landmarks can easily be mistaken for abnormal or pathologic conditions. In the chapters that deal with various dental pathologic conditions, the author gives a definition or a description of the condition, also the etiology, symptoms and roentgenographic observations. These are followed by profuse illustrations covering or illustrating the point in question. As in the first edition the author clings to certain terms that are obsolete and should be changed, he uses the term premolar instead of bicuspid and refers to mandibular and maxillary molars instead of upper and lower molars.

The Localization of Sound By H. E. O. James Medical Research Council Reports of the Committee upon the Physiology of Hearing III Special Report Series No 207 Paper Price 9d Pp 38 with illustrations London His Majesty's Stationery Office 1936

If from a source of sound two equal tubes are led one to each ear of an observer, the sound will be said to be heard in the middle of the head. If one tube is shortened, the sound will be heard on that side even though the source of sound remains the same distance from the observer. Instruments of this character have a practical military significance in that they permit accurate localization of submarines and airplanes. By means of sound-collecting devices the observer 'tunes in' the sound of a distant airplane, let us say and finally getting the sound to appear as if it were in the middle of his head, he is able to calculate with a fair degree of accuracy from what direction it is coming and which way it is going. The question arose as to what the effect of other sounds on an observer so occupied would be on the accuracy of his determinations, and the larger question of protection against industrial hazards in the presence of noise also arose. The problem of 'attunement' came up. An observer who localizes a sound as if it were in the middle of his head will not do so if one ear has been exposed to sound for a short time before this. He has become 'attuned.' The author experimented on the accuracy of localization and on the speed with which it returns after exposing one and both ears to sounds with a number of various types of apparatus. Different kinds of sounds were used. The effect of exposing the observer first to sounds of different intensities and of varying durations and different frequencies, and the effect of the subsequent 'attunement' on accuracy of localization, were determined. The greater question of auditory fatigue was considered. Does an observer exposed first of all to a sound in one ear and then bilaterally stimulated refer it to the unexposed ear because the first ear is tired? That is, is auditory fatigue present? If the proper explanation is auditory fatigue why does the patient suffer from diminution in hearing ability in the opposite

unstimulated ear? Apparently auditory fatigue, better called as the author says "experimental deafness" cannot be entirely explained by fatigue of the end organ. There must be, some observers feel, an additional central factor. These and a number of other interesting questions are raised to intrigue the interest of otologists, psychologists and physiologists in the fundamental mechanism of hearing. More valuable than the practical results of these experiments is the feeling that much that is of importance will come in the future from further work in this only recently explored field.

Nouvelle pratique dermatologique Publiée par MM. Darier, Sabouraud, Gougerot, Milian, Pautrier, Ravaut, Sézary, Clément, Simon, Secrétain, général, Clément, Simon. Tome I. Table générale des huit volumes du traité. **Dermatologie générale** Par MM. J. Darier, A. Clément, A. Flandin, A. Tzanck. Half Cloth Price 300 francs Pp 720 with 220 illustrations. Tome II. **Dermatoses parasitaires** **dermatoses microbennes** (début) Par MM. H. Gougerot, M. Langeron, A. Lévy, Franckel, A. Louste, G. Milian, P. Pignot, H. Rabeau, P. Ravaut, E. Rivalier, B. Sabouraud. Half Cloth Price 300 francs Pp 948 with 555 illustrations. Tome III. **Dermatoses microbennes** (suite) Par G. Barbier, L. Chateiller, Mme. Cherrel, Bodin, H. Galliard, H. Gougerot, G. Lacapère, G. Milian, L. M. Pautrier, L. Queyrat, E. Rivalier, P. Vigne. Half cloth Price 300 francs Pp 1027 with 343 illustrations. Paris. Masson & Cie 1936.

"The present work is destined to replace the *Pratique dermatologique* published in 1900 under the direction of Besnier, Brocq and Jacquet, and which in its time, marked a date in the history of dermatology." Thus begins the introduction to this monumental work in eight volumes. Careful examination of the first three volumes justifies the statement that "the directors of this treatise have undertaken and have realized this task." One notes with regret that of the eighty-nine notable collaborators Paul Ravaut, Audrey, Barbier, Lacapère, Louste, Montlaur, Miget and Queyrat have passed away since the beginning of the gigantic undertaking. The first volume contains a table of contents for the entire eight volumes. One has an opportunity, thereby, to envision the comprehensiveness and the completeness of the work. An alphabetical index will appear in the eighth volume. The books are beautifully bound and are printed on the best of paper, with numerous illustrations done with the most modern technic. One regrets, therefore that the directors saw fit to include a group of ancient, meaningless drawings on pages 493 to 497.

The first volume comprises a historical review of the classification of the dermatoses, macroscopic anatomy and histology of the skin, physiology, histopathology, lesions of the adnexa, etiology and general pathology. A chapter on diagnosis and another on therapeutics complete the volume.

The second volume opens with ninety-eight pages devoted to the animal parasites by Louste and Lévy-Franckel. The chapter is of such unusual excellence that an attempt was made to find an omission none but bird scabies was discovered. Sabouraud continues with a chapter on mycoses of the scalp done as only this great master of the fungous diseases could do it. This chapter is followed by a series of exhaustive articles on all phases of the mycotic diseases by Sabouraud, Rivalier, Pignot, Gougerot, Ravaut, Rabeau and Langeron. If one had no other reference book one could get on well with this volume alone, aided by the lengthy bibliography. The remaining pages in the volume are devoted to a monograph on syphilis by Milian. The only criticism one could make of the monograph is that the bibliography is scanty.

The third volume has the first 200 pages given over to a continuation of the monograph by Milian, followed by a short article by Lacapère on African and Asiatic syphilis. Following this are excellent articles on yaws, leishmaniasis, oriental sore, trypanosomiasis and the fusospirillar infections. The bulk of the volume is taken up by a monograph on the entire field of cutaneous tuberculosis by Pautrier. This chapter is done in a most authoritative manner, well documented and beautifully illustrated. Pautrier has included lupus erythematosus, as he has been a partisan of the tuberculous origin of the disease for thirty years. After an exhaustive analysis of all the views as to etiology, Pautrier says "There remains the tuberculous theory, it is the most logical, the most reasonable, the one which best satisfies the spirit, the one which unites the maximum of probability with the beginnings of proof." The article is brought to a close with an excellent discussion of granuloma

annulare, which has only an "uncertain and debatable connection with tuberculosis." Gougerot contributes a valuable article on leprosy, and Rivalier closes with an excellent and beautifully illustrated chapter on chancroidal infections.

The dermatologic world is greatly indebted to the French school of dermatology for having produced such handsome and valuable volumes. The arrival of the remaining volumes will be eagerly awaited.

Dental Infection and Systemic Disease. By Russell L. Haden, M.A. M.D. Chief of the Medical Division, Cleveland Clinic, Cleveland, Ohio. With a foreword by Dr. Edward C. Rosenow. Second edition. Cloth. Price \$2.50. Pp. 163 with 63 illustrations. Philadelphia: Lea & Febiger, 1935.

By his studies and clinical data, the author evaluates the present status of dental infection in relation to the clinic. He speaks of the education of dentists, physicians and public to the danger of infected teeth as yielding beneficial results, shown by the decreased incidence of pulpless teeth. This is also due to dental advancement in that the dentist is conserving the teeth and their pulps to a greater degree. The volume offers a complete guide for the research worker whose interest may lead him to corroborate the painstaking work of the author and whose conclusions may stimulate further interest in preventive dentistry.

Biologische Wirkungen des Alkohols auf den Stoffwechsel. Ergebnisse experimenteller Untersuchungen in dem von mir geleiteten Laboratorium unter Verwendung der Wismarschen Mikromethode der Blutalkoholbestimmung über Wirkungen des Alkohols auf den Stoffwechsel. Über die Verwertung des Alkohols bei der Muskelarbeit, über Beziehungen des Blutalkoholgehaltes zum Rauschzustand, über Insulinbehandlung der Alkoholintoxikation und die Insulinblockade der Ganglienzellen. Von Adolf Bickel, Professor der pathologischen Physiologie an der Universität Berlin. Paper. Price, 90 pfennigs. Pp. 31. Leipzig: Georg Thieme, 1935.
